KEY WORDS
Hydrogen sulfide (H₂S); Gasotransmitters; H₂S prodrugs; H₂S-hybrid nonsteroidal anti-inflammatory drugs; Controllable H₂S prodrugs; Hydrolysis-based H₂S prodrugs

Abstract  Hydrogen sulfide (H₂S) is recognized as one of three gasotransmitters together with nitric oxide (NO) and carbon monoxide (CO). As a signaling molecule, H₂S plays an important role in physiology and shows great potential in pharmaceutical applications. Along this line, there is a need for the development of H₂S prodrugs for various reasons. In this review, we summarize different H₂S prodrugs, their chemical properties, and some of their potential therapeutic applications.

1. Introduction

Hydrogen sulfide (H₂S), a well-known lethal, toxic gas with the smell of rotten eggs, is recognized as one of the three gasotransmitters in mammals, which also include nitric oxide (NO) and carbon monoxide (CO). The literature evidence suggests that hydrogen sulfide possesses the following activities: anti-inflammatory, anti-tumor, ion channel regulation, cardiovascular protection, and antioxidation. However, the exact role that hydrogen sulfide plays depends on the specific circumstance, its concentration, and the interplays with other signaling molecules, especially NO and CO. This is a major area of research in developing hydrogen sulfide-based therapeutics, but is beyond the scope of this review. Another major issue is finding appropriate ways of delivering hydrogen sulfide to the relevant location, at the right concentration, and with the appropriate pharmacokinetics. Much of this issue stems from the fact that it is unrealistic to use gaseous hydrogen sulfide itself or its salt such as sodium sulfide in therapeutic applications in human. Thus there is a great deal of interest in searching for appropriate hydrogen-sulfide-releasing agents, which are commonly referred to as H₂S donors or prodrugs. This review provides a summary of developments in this field mostly during the last five years with a focus on the chemistry concepts.

1.1. H₂S chemistry

H₂S is a weak acid and soluble in water (up to 80 mmol/L at 37 °C). The pKₐ values (37 °C) for the first and second dissociation steps are about 6.88 and 19, respectively. Under physiological conditions (pH = 7.4), H₂S largely exists in two forms: the neutral molecular form (H₂S) and an ionic form (HS⁻) (Scheme 1). S²⁻ is a very minor component simply because of the second pKₐ being very high. However, the bioactive form is still unknown, and the term H₂S is usually used referring to the total sulfide species. Although H₂S has good solubility in water, it is still very unstable in solution. It is easy oxidized in the presence of oxygen. In addition, the volatility of hydrogen sulfide adds complications to experiments. For example, half of the dose of H₂S could be lost in 5 min from open cell culture wells. H₂S concentration can decrease so rapidly that the precise measurement of H₂S concentration is a great challenge in this field.

1.2. H₂S biology

In mammals, three enzymes are involved in sulfur-containing amino acid metabolism and thus responsible for the in vivo production of H₂S. Two of them are pyridoxal-5’-phosphate (PLP)-dependent enzymes: cystathionine β-synthase (CBS) and cystathionine γ-lyase (CSE). CBS is expressed predominantly in the central nervous system (CNS). Relatively high concentrations (47 µmol/L to 166 µmol/L) of H₂S have been observed in the brains of mammals. The normal cellular function of CBS is in the trans-sulfuration pathway, catalyzing the condensation of homocysteine with serine to form cystathionine. In the 1980s, CBS isolated from rat liver and kidney was reported to produce H₂S from cysteine. In contrast to CBS, CSE is mainly responsible for the production of H₂S outside of the CNS. CBS and CSE share a common feature of catalytic promiscuity. The relative contributions of CBS and CSE to H₂S generation at low homocysteine concentration are about 7:3. However, CBS activity is confined to chemical transformations at the β-position, while CSE is proficient at catalyzing reactions at the β- and γ-carbons of substrates. Furthermore, because homocysteine appears to be unable to bind to the site at which the external aldimine with PLP is formed in CBS, CSE’s contribution to the H₂S pool is increased under conditions of moderate and severe hyperhomocysteinemia. A third H₂S-producing enzyme, 3-mercaptoppyruvate sulfurtransferase (3MST), was thought to exist, as H₂S was not depleted in CBS knockout mouse brain. 3MST, a PLP-independent enzyme, is localized in the neurons in the brain along with cysteine aminotransferase (CAT), while CBS is localized in the astrocytes, a type of glia, in the CNS. 3MST and CAT are also found in the vascular endothelium. CAT catalyzes the reaction of L-cysteine with α-ketoglutarate to form 3-mercaptoppyruvate (3MP), which is further catalyzed by 3MST to generate H₂S in the presence of thiol and reducing agents (Fig. 1). Overall, H₂S production in mammals is intimately connected to the metabolic pathways of sulfur containing amino acids. The PLP-dependent trans-sulfuration pathway, which contains both CBS and CSE for H₂S production, is localized in the cytosol. H₂S synthesis via CAT and 3MST occurs in the cytosol and mitochondria.

2. H₂S prodrugs

In the past several years, many series H₂S prodrugs have been developed. They could be divided into three general classes: plant-derived natural products, hydrolysis-based H₂S prodrugs, and controlled-release H₂S prodrugs.

2.1. Plant-derived natural products

Allium vegetables, represented by garlic and onions, have long been considered as salubrious foods that have anti-inflammatory functions, and their active ingredients have been shown to reduce the risk of diabetes and cardiovascular diseases. It was not until 2007 that studies from Kraus’ group showed that the...
vaseoactivity of garlic compounds was correlated with H$_2$S production\textsuperscript{35}, which suggested that the major beneficial effects of allium vegetable diets are mediated by the biological production of H$_2$S from organic polysulfides.

To date, several sulfur-containing components from garlic or garlic preparations have been identified ($\gamma$-glutamylcysteines and alliin in the intact garlic; ajoene and allyl mercaptan in the steam-distilled garlic oil; $\gamma$-allyl-cysteine and $\gamma$-allyl-mercaptocysteine in the aged garlic extract; and methiin in the garlic homogenate). Among all the different components, only three of them, $\gamma$-allyl-cystein (SAC), diallyl disulfide (DADS), and diallyl trisulfide (DATS) have been shown to have pharmacological effects, which are correlated with the H$_2$S signaling pathway\textsuperscript{41,42}. DADS and DATS are major components of garlic oil\textsuperscript{39}, and are derived from allisin, which is unstable in H$_2$O.

Organic polysulfides DADS and DATS act as H$_2$S donors when they react with biological thiols including GSH, or by human red blood cells via glucose-supported reactions. It is proposed that DADS undergoes nucleophilic substitution at the $\alpha$-carbon and yield a key intermediate allyl perthiol to form H$_2$S (Scheme 3). The chemical conversion of organic polysulfides to H$_2$S is facilitated by allyl substituents and dependent on the number of tethering sulfur atoms. Another study of DADS found that the hepatocyte cytotoxicity of DADS might be attributed to the inhibition effect of H$_2$S on cytochrome oxidase\textsuperscript{44}, suggesting biological production of H$_2$S from DADS.

The third sulfur-containing compound in allium vegetables related to H$_2$S production is $\gamma$-allyl-cysteine (SAC), a reduced form of allisin, which is the major component in aged garlic extract. Studies from Zhu's group\textsuperscript{32,45} showed that SAC and CR-SPRC, a cysteine analog of SAC, upregulated CSE expression and increased plasma H$_2$S concentrations. Rats used in an acute myocardial infarction and heart failure model were treated with SAC or CR-SPRC, respectively. It was found that SAC and its analog significantly lowered mortality and improved cardiac function. The activity of CSE, CAT, GSH, and plasma H$_2$S concentration were increased in SAC-pretreated and CR-SPRC-treated rats, suggesting its cardioprotection effect via a H$_2$S-mediated pathway. However, there is no report on H$_2$S production directly from SAC in the biological systems.

Recently, Kondo et al.\textsuperscript{46} published a H$_2$S prodrug: SG-1002 (Fig. 2), which is a polysulfur mixture containing 92% $\alpha$ sulfur, 7% sodium sulfate and a trace amount of other sulfur derivatives. In one study, SG-1002 was administered to C57BL/6J or CSE knockout mice to investigate the effects of genetic modulation of CSE and exogenous H$_2$S in a pressure overload-induced heart failure model. It was found that CSE knockout mice exhibited significantly greater cardiac dilatation and dysfunction than wild-type mice after transverse aortic constriction, and cardiac-specific CSE transgenic mice maintained cardiac structure and function after transverse aortic constriction. H$_2$S afforded by SG-1002 could upregulate the vascular endothelial growth factor (VEGF)-Akt-endothelial nitric oxide synthase (eNOS)-nitric oxide (no)-cGMP pathway with preserved mitochondrial functions, attenuated oxidative stress, and increased myocardial vascular density. The results show oral H$_2$S therapy prevents the transition from compensated to decompensated heart failure in part via upregulation of endothelial nitric oxide synthase and increased nitric oxide bioavailability. However what needs to be noted concerning these studies is that the mechanism of H$_2$S release from SG-1002 is not described. More studies are needed to prove the correlation of H$_2$S production and the observed pharmacological effects.

### 2.2. Hydrolysis-based H$_2$S prodrugs

Hydrolysis-based H$_2$S prodrugs primarily consist of four classes of analogs: namely, inorganic sulfate salts including NaHS, Na$_2$S and CaS; Lawesson's reagent and analogs; 1,2-dithiole-3-thiones (DTTs); and arylthioamides derivatives. For arylthioamides derivatives, some classified them as thiol-activated H$_2$S donors. Since these compounds are easily hydrolyzed to generate H$_2$S in PBS buffer, they are summarized in this section.

#### 2.2.1. Inorganic sulfate salts

NaHS and Na$_2$S are two widely used H$_2$S donors in basic research. Upon hydrolysis, both compounds could generate H$_2$S quickly in PBS buffer (pH 7.4). In aqueous state under physiological pH, the ratio of HS\textsuperscript{-}/H$_2$S is around 3:1\textsuperscript{19,47}.

NaHS and Na$_2$S have been extensively used in studying the biological effect of hydrogen sulfide. For example, in an ovalbumin-treated rat model\textsuperscript{68}, NaHS treatment could increase peak expiratory flow (PEF), and decrease goblet cell hyperplasia, collagen deposition score, the total cells recovered from bronchoalveolar fluid, and influx of eosinophils and neutrophils. Additionally, administration of NaHS also significantly attenuated activation of pulmonary inducible nitric oxide synthase (iNOS). Those results suggested that H$_2$S possessed anti-inflammatory and

anti-remodeling effect in asthma pathogenesis, presumably by the cystathionine-gamma-lyase (CSE)/H₂S pathway. Using NaHS as a H₂S donor, Du et al. examined the possible role of H₂S in the pathogenesis of oleic acid (OA)-induced acute lung injury (ALI) and its regulatory effects on the inflammatory response. Intraperitoneal injection of NaHS (56 μmol/L) into OA-treated rats increased the pressure of oxygen in the arterial blood (PaO₂), reduced the lung wet/dry ratio and alleviated the degree of ALI. Additionally, NaHS decreased inflammatory cytokine such as IL-6 and IL-8 levels and increased anti-inflammatory cytokine IL-10 levels in the plasma and lung tissues. Similarly, Na₂S inhibited IL-1β levels and significantly increased anti-inflammatory cytokine IL-10 levels in an acute lung injury model.

In addition to anti-inflammatory effect, NaHS or Na₂S also showed pro-inflammatory ion channel regulation, cardi-vascular, and neurogenic regulation effects. Although NaHS and Na₂S presented promising biological results both in vitro and in vivo, the likelihood of their use in clinical applications is small due to reasons such as release kinetics, smell, lack of ability to target, and difficulty in controlling its concentration because of hydrogen sulfide's volatility. Nevertheless, encouragingly, a sodium sulfide solution (IK-1001) for intravenous injection has successfully completed a phase I clinical trial, thus pointing to the possibility of applications in well-defined situations.

Another potential inorganic H₂S donor is calcium sulfide (CaS), which is one of the effective components in a traditional medicine, hep sulphuris calcareum. Compared to NaHS and Na₂S, CaS is chemically more stable. However, there is only limited information on the effectiveness of CaS as H₂S donor.

2.2.2. Lawesson's reagent and analogs

Lawesson's reagent, which is widely used for sulfurization in organic synthesis, also releases H₂S upon hydrolysis, and has been used as a H₂S donor in some studies. Compared to inorganic sulfide, the release rate with Lawesson's reagent is much slower. After incubation of Lawesson's reagent in buffer or rat liver homogenate for 60 min, the conversion to H₂S was about 18% or 11%, respectively. In work by Medeiros et al., Lawesson's reagent was used as H₂S donor to anesthetized rats could also boost the concentration of H₂S in plasma to around 75 μmol/L at the 30 min point, and the concentration remained elevated (above 40 μmol/L) for more than 180 min. Additionally, GYY4137 did not cause any significant cytotoxic effect, or alter the cell cycle profile or p53 expression of cultured rat vascular smooth muscle cells. However, NaHS was previously reported to induce apoptotic cell death of cultured fibroblasts and smooth muscle cells. The differences in the safety profile between GYY4137 and NaHS may be attributed to the differences in H₂S release rate and the concentration of H₂S generated.

In work published by Liu et al., GYY4137 was employed as a H₂S donor to investigate its effects on CVB3-induced myocarditis and possible underlying mechanisms. The results showed that GYY4137 suppressed CVB3-induced secretion of enzymes implicated in cardiocyte damage including LDH, CK-MB, and decreased the level of pro-inflammatory cytokines, such as TNF-α, IL-1β and IL-6. Moreover, GYY4137 also inhibited the activation of NFκB and the IkB degradation induced by CVB3. Notably, the phosphorylation of p38, ERK1/2 and JNK1/2 induced by CVB3 was also suppressed by GYY4137. Taken together, GYY4137 exerted its anti-inflammatory effect in CVB3-infected cardiomyocytes, which was possibly associated with H₂S generation by GYY4137. The anti-inflammatory mechanism may be associated with the inhibition of NFκB and the mitogen-activated protein kinase (MAPK) signaling pathway.

Additionally, at a concentration of 400 or 800 μmol/L, GYY4137 also showed some anti-cancer effect with 30%–70% death in seven different human cancer cell lines (HeLa, HCT-116, Hep G2, HL-60, MCF-7, MV4-11 and U2OS) and no effect on the survival of normal human lung fibroblasts (IMR90, WI-38). In contrast, NaHS did not show any anticancer effect (400 μmol/L), and only showed less potent growth inhibition (15%–30%, 800 μmol/L). The author attributed such difference to the different H₂S release rate between GYY4137 and NaHS. Incubation of GYY4137 (400 μmol/L) in culture medium released low concentrations (<20 μmol/L) of H₂S, with the concentration sustained over a period of 7 days. In contrast, incubation of NaHS (400 μmol/L) in the same way led to much higher concentrations (up to 400 μmol/L) of H₂S with a much shorter duration (1 h). It is well-known that the effect of H₂S is concentration-dependent with high concentrations (above 250 μmol/L) being toxic, thus it is easy to understand that release kinetics and peak concentration would make much difference to the overall effect of a H₂S donor.

The in vivo antitumor effect of GYY4137 was also evaluated. In a xenograft mice model (HL-60 and MV4-11 cells), GYY4137 could significantly inhibit tumor growth at dosages of 100–300 mg/kg/day.

Despite all the success described above, other independent studies sometimes showed opposite effect when NaHS was used as a donor. For example, H₂S in the form of NaHS showed protective influence on neuroinflammation in a model of experimental autoimmune encephalomyelitis, and reduced the level of pro-inflammatory cytokine IL-1β.
effect for colon cancer cells, increased proliferation of colon cancer cells, and reduced apoptosis in several cell lines. These disparate observations may be due to the use of different H2S donors, which release H2S at different rates, give different byproducts, and have different peak concentrations. Although ZYJ1122 (Fig. 3), an analog of GYY4137 lacking sulfur, was inactive in all cancer cell lines tested, it is unclear what byproducts GYY4137 would generate in cells, because the metabolism for GYY4137 is expected to be complicated. Additionally, it should be kept in mind that the percentage of hydrolysis for GYY4137 is low, which means that the majority of GYY4137 remained in the cells. Since relatively high concentrations of GYY4137 were used (400 and 800 μmol/L), it is entirely possible that the observed anticancer effect may be caused by GYY4137 itself or its metabolism products, and not necessarily the released H2S. The convoluted situation with the observed effects of “H2S” is a strong indication that future experiments need to be benchmarked against a standard and standard conditions with careful control and documentation of concentrations.

In order to tune the H2S release capability of GYY4137, structural modifications on the phosphorodithioate moiety were made to GYY4137 to afford a series of O-substituted phosphorodithioate-based H2S donors (Fig. 3). Their H2S releasing properties were evaluated by fluorescence methods. After incubation (100 μmol/L) in PBS buffer (pH 7.4) for 3 h at room temperature, N,O-diarylated donors and GYY4137 could release H2S with a final concentration of around 800 nmol/L. However, the O-alkylated donors showed very weak H2S production (data not shown in the paper). The protective effects of N,O-diarylated donors against H2O2-induced oxidative damage in H9C2 cells were investigated. Specifically, the donors were incubated with the cells for 24 h before H2O2 was added. Then cell viability was determined by the CCK-8 assay after incubation for another 5 h. The results showed that in the absence of a H2S donor, cell viability decreased by about 65%. In the presence of H2S donors (N,O-diarylated donors, GYY4137 and NaHS), a much higher level cell viability was observed, especially for one N,O-diarylated donor, which increased the cell viability to about 95% at the concentration of 100 μmol/L. These results suggested that the H2S donors did present protective effects against oxidative injury. As mentioned above, the biological results obtained for these donors should be carefully associated with the generation of H2S. Further experiments may be needed to clarify this.

2.2.3. Arylthioamides derivatives

A series of arylthioamides were synthesized by Vincenzo Calderone et al., and their H2S release properties were evaluated. The synthesized compounds were incubated with or without l-cysteine in PBS buffer at 37 °C, and H2S release was recorded by amperometry. The results showed that compounds 1–3 (Fig. 4) did not generate a detectable level of H2S (<2 μmol/L) in the absence of l-cysteine; however, they did release H2S in the presence of l-cysteine with Cmax of about 10 μmol/L. For compounds 4 and 5 with strong electron-withdrawing substituents, no detectable levels of H2S were observed with or without l-cysteine. Based on those results, it seems that the H2S release mechanism for arylthioamides is thiol-activated, and Xian et al. did classify arylthioamides as thiol-activated H2S donors. However, some analogs in this series also generated detectable amounts of H2S in the absence of l-cysteine, especially compound 12, which did not show any difference in the amount of H2S released with or without l-cysteine. It is well characterized that hydrolysis of thioacetamide would lead to H2S formation. So it could be concluded that the hydrolysis of arylthioamides could also give H2S. Actually, Wallace et al. classified these compounds as hydrolysis-based H2S donors. It may be more reasonable to say that both mechanisms contribute to H2S generation because there is no clear evidence to exclude either.

After confirmation of H2S release from arylthioamides, compound 1 was chosen for further pharmacological studies. It strongly abolished the noradrenaline-induced vasoconstriction in isolated rat aortic rings and hyperpolarized the membranes of human vascular smooth muscle cells in a dose-dependent fashion. After oral administration of compound 1, the systolic blood pressure of the animals was significantly reduced. These findings make arylthioamides promising H2S donors for further study.

No matter what the H2S release mechanism for arylthioamides is, it should be noted that incubation of 1 mmol/L of the donors only release H2S with a Cmax value of about 10 μmol/L, which means that the major species in solution is still the donor itself. Thus it is still premature to associate the observed bioactivities with the generation of H2S alone, because the bioactivities may be caused by the donor itself or a combination of various species. Actually, this issue is quite common among the organic H2S donors. More detailed and well-designed control experiments are needed to address this issue.

2.2.4. 1,2-Dithiole-3-thiones and H2S-hybrid nonsteroidal anti-inflammatory drugs

1,2-Dithiole-3-thiones (DTT) has also been used as a H2S donor. Although its H2S-release mechanism is still not fully clarified, it is widely accepted that hydrolysis is part of the underlying mechanism for the generation of H2S from DTT.

The use of nonsteroidal anti-inflammatory drugs (NSAIDs) suffers from unacceptable risk of gastrointestinal ulceration and bleeding. In order to reduce such side effects, DTTs have been conjugated to NSAIDs to form HS-hybrid NSAIDs (HS-NSAIDs, Fig. 5), which showed significant reduction of gastrointestinal damage compared to the parent NSAIDs. In addition, HS-NSAIDs also boosted the anti-inflammatory effect of their NSAIDs counterparts. In a work by Fiorucci et al., DTT was conjugated to diclofenac to afford a HS-NSAID-hybrid ATB337, and its anti-inflammatory effect was investigated along with diclofenac in rats. In a rat air pouch model, orally

\[ \text{Ph-H} \quad \text{Phosphorodithioate} \]
administered ATB-337 dose-dependently suppressed the activity of both COX-1 and COX-2, and the efficiency was comparable to that of the diclofenac. Additionally, pretreatment with ATB-337 and diclofenac led to a reduction of carrageenan-induced paw swelling volume. Notably, pretreatment with ATB-337 at 10 μmol/kg achieved a reduction in edema formation comparable to that seen with diclofenac at 30 μmol/kg. This enhanced potency was probably associated with the generation of H₂S from ATB-337.

An enhanced anti-inflammatory effect was also observed for ATB-429. In addition to their anti-inflammatory effect, other HS-NSAIDs including HS-sulindac (HS-SUL), HA-aspirin (HS-ASA), HS-ibuprofen (HS-IBU), and HS-naproxen (HS-NAP), were also reported to exhibit anti-proliferative effect against human colon, breast, pancreatic, prostate, lung, and leukemia cancer cell lines. The conjugation with 5-(4-hydroxyphenyl)-1,2-dithiol-3-thione (ADT-OH) significantly increased the growth inhibitory effect of NSAID by 28- to >3000-fold.

Along the line of NSAID's antiproliferation effect, Kashif et al. prepared a compound NBS-1120 (Fig. 6), which could release NO, H₂S and aspirin at the same time. NBS-1120 inhibited HT-29 colon cancer growth with IC₅₀ values of 45.5 ± 2.5, 19.7 ± 3.3, and 7.7 ± 2.2 nmol/L at 24, 48, and 72 h time points, respectively. This is the most potent NSAID-based anticancer agent so far. Mechanistic studies showed that NBS-1120 induced apoptosis, and arrested the cells at G₀/G₁ phase. NBS-1120 also showed promising in vivo antitumor effect. It significantly inhibited tumor growth by 85% in mice bearing a human colon cancer xenograft.

Accumulating evidence supports that H₂S plays a vital role in the modulation of mitochondrial cell death pathways and in the regulation of cellular bioenergetics. Multiple studies revealed that H₂S donors help maintain mitochondrial integrity, reduce the release of mitochondrial death signals, and attenuate mitochondrially-regulated cell death responses of various types. Szabo et al. prepared a compound AP39 (Fig. 6) with two moieties: ADT-OH for H₂S generation and triphenylphosphinium (TPP) for mitochondrial targeting. Cell imaging studies confirmed that AP39 was primarily internalized in mitochondria. After confirming the mitochondria-targeting H₂S delivery, compound AP39 was employed to investigate its effect on bioenergetics, viability, and mitochondrial DNA integrity in bEnd.3 murine microvascular endothelial cells in vitro. At a
Hydrogen sulfide prodrugs

The goal of controllable H\(_2\)S prodrugs was to develop H\(_2\)S prodrugs, which are stable in aqueous solutions and during sample preparation\(^{15}\). The prodrugs can release H\(_2\)S in the presence of triggers, which could be enzymes, pH, biomolecules, UV-light, and others. However, this is still a great challenge in this field. Currently, there are three examples: thiol activation, light activation, and bicarbonate activation.

2.3.1. Thiol activation

In 2011, Xian\'s group\(^{85}\) developed the first thiol activated H\(_2\)S prodrugs: N-mercapto (N-SH)-based derivatives. The strategy was based on the instability of the N-SH bond. The thiol group was first protected with acyl groups, and then the protected nitrogen-sulfur bond could be stable to some degree. In the presence of thiol species in the biological system, H\(_2\)S release can be triggered through reduction. A detail mechanism is shown in Scheme 4. The prodrug is first activated by thiol exchange between a thiol species (cysteine or GSH) and the prodrug to generate S-acylated cysteine and N-mercaptobenzamide. Then one of the intermediates, N-mercaptobenzamide, reacts with cysteine to form cysteine perthiol, which is followed by interaction with cysteine to release H\(_2\)S. In this mechanism study, the Xian\'s group found that perthiol could also be a key intermediate in H\(_2\)S generation. In 2013, Xian\'s lab\(^{86}\) published a series of perthiol-based H\(_2\)S prodrugs, with a release mechanism similar to that of the previous example. Briefly, thiol exchange initiates the reaction to form penicillamine perthiol intermediate, which is followed by thiol attack again to produce either a disulfide and H\(_2\)S (Scheme 5, pathway a.), or a new perthiol, which would interact with another thiol species to release H\(_2\)S (Scheme 5, pathway b).

2.3.2. Photo-induced H\(_2\)S prodrugs

The second type of controllable H\(_2\)S prodrugs is light-activated H\(_2\)S prodrugs. Recently, there have been two examples published. The first one is gem-dithiol-based H\(_2\)S prodrugs. In 2013, Xian and coworkers\(^{88}\) identified geminal-dithiol (gem-dithiol) as a structure, which could release H\(_2\)S in aqueous solution. Then a photo-cleavable structure (a 2-nitrobenzyl group) was introduced to protect perthiol. Regeneration leads to H\(_2\)S release. Based on this strategy, several gem-dithiol-based H\(_2\)S prodrugs were prepared. Methylene Blue assay indicated that 200 μmol/L prodrugs could generate a peak concentration of 36 μmol/L H\(_2\)S under UV irradiation (365 nm). However, there are two

![Scheme 4 Proposed N-SH H\(_2\)S prodrugs H\(_2\)S releasing mechanism.](image-url)
obvious drawbacks of these prodrugs. First, H₂S release rate depends on the hydrolysis of gem-dithiol, which is nearly fixed. Second, the reactive byproducts 2-nitrosobenzaldehyde can react with H₂S, which results in diminishing H₂S generation. Later, Nakagawa’s group investigated another type of photo-induced H₂S prodrugs: ketoprofenate-caged H₂S prodrugs (Scheme 7). Upon UV irradiation (300–350 nm) for 10 min, 500 μmol/L of the prodrug would generate 30 μmol/L of H₂S in fetal bovine serum together with 2-propenylbenzophenone and CO₂. These two photo-induced H₂S prodrugs successfully demonstrated the photo-triggering concept, but the cytotoxicity induced by UV-light could limit their applications.

2.3.3. Thiolamino acid

Thiolamino acids as the third class of controllable H₂S-releasing prodrugs were first reported by Giannis and coworkers in 2012. Thioglycine and thiovaline were shown to release H₂S in the presence of bicarbonate under physiological conditions. The mechanism is shown in Scheme 8.

The thiolamino acids interacted with bicarbonate to form carbamate intermediates, which undergoes a cyclization reaction leading to N-carboxyanhydride and H₂S release (Scheme 8). ³¹H NMR spectroscopy studies were carried out to measure the decomposition of thioglycine in the presence of NaHCO₃. In a 40 mmol/L bicarbonate solution at 40 °C, 35% N-carboxyanhydride were formed in 72 h. Since there is a high bicarbonate concentration (27 mmol/L) in blood at physiological pH, thiolamino acids can be an H₂S prodrug candidate. Giannis and coworkers compared the H₂S-releasing capacities of thiolamino acids with that of GYY4137. About 50 μmol/L H₂S from 100 μmol/L of thioglycine could be detected by a fluorescent probe dibromobimane, while GYY4137 liberated less H₂S at the same condition. Giannis and coworkers also tested the pharmacological benefits of such H₂S prodrugs. Results showed that thioglycine and thiovaline could enhance intracellular cyclic guanosine monophosphate (cGMP) concentration and promote vasorelaxation. One possible limit of the bicarbonate activated H₂S prodrugs stems from the reactivity of thiolamino acids, which could quickly undergo amidation reaction under aerobic conditions (Scheme 9).
3. Conclusions

The review gives a brief summary of the current state of H₂S prodrugs. These prodrugs not only play an important role as research tools but also are promising candidates for the development of therapeutic agents. All prodrugs have their advantages, and also limitations. The most challenging in this field is still the development of prodrugs with precise control of the release kinetics so that they mimic endogenous H₂S generation. The effects of prodrugs themselves and the byproducts need to be taken into consideration in all the biological experiments. Thus, new hydrogen sulfide prodrugs with improved control of release kinetics are needed in this field.
