ONTOLOGY OF GEOLOGICAL MAPPING

by

TYLER BOYD

Under the Direction of Dr. Hassan Babaie

ABSTRACT

In this thesis, an ontology for the geological mapping domain is constructed using the Protégé ontology editor. The Geological Mapping ontology is developed using terms and relationships, and their properties, as they relate to creating a geologic map. This vocabulary is semantically modeled in the ontology using Web Ontology Language (OWL). The purpose of this thesis is to exemplify how an ontology can be designed and developed to represent geological knowledge as it relates to mapping.

DEDICATION

I dedicate this thesis to my loving wife, Shannon, for all of her help and support over the past few years.

ACKNOWLEDGEMENTS

I would like to thank all who have made this thesis possible, without their help this work would not have been accomplished.

I would first like to thank my advisor Dr. Hassan Babaie, for providing me with his guidance, encouragement, and assistance. Through his experience and suggestions, I was able to make my thesis what it is today. My desire to pursue a Master's degree would not have sustained without his continuous support.

I would also like to thank my Thesis Committee members, Dr. Paulo Hidalgo-Odio and Dr. Brian Meyer for their roles in helping guide me through the Master's program and the completion of my thesis.

This work was conducted using the Protégé resource, which is supported by grant GM10331601 from the National Institute of General Medical Sciences of the United States National Institutes of Health.

1 INTRODUCTION

1.1 Purpose of the Study

The purpose of this thesis is to establish an ontology for geological mapping that has not yet been created. This new ontology for geological mapping goes beyond earlier ontologies that simply dealt with recording site data or correlating information from one map to the adjacent map. The goal of this ontology is to make it so a newly created map inherently has semantic meaning. The semantic capabilities of this ontology far exceed those present in other ontologies by actually enabling individual geological features on a map to understand their geological meaning as they relate to themselves and all other features on the map. This permits a non-geologist to discover what is being represented on the map and how it relates to other features, similar to how a geologist would. It would also allow a geologist, seeking complex information about an area or region specific to their study, to quickly and effectively retrieve, via query, all information and related information, just by asking the knowledge base associated with that ontology. The level of difficulty and specificity of queries made within the Ontology of Geological Mapping far surpasses those able to be made in a standard data-base, due to the information within the knowledge base actually knowing how all parts within itself relate. Developing this ontology is important for overcoming the limitations of paper maps and providing a tool capable of semantic reasoning, where both geologists and non-geologists can gain a better understanding of the information contained within geologic maps.

Geologic mapping is an essential part of understanding an area of study in geology. Over the years, there have been countless maps created across the globe. These maps were developed using basic tools and technologies that do not directly allow software to acquire an understanding

of the geological features that have been placed on the maps. The development of an ontology for geologic mapping would transform a map from a 2D image with attached map key, to a map that is able to find specific information that fits the answer to a complex query about it. This is due to the fact that an ontology makes it so the information on the map is semantically connected to all other relevant information on the map. An ontology would create a semantically-aware data collection and storing system for geologic maps. It would also unify and relate the terms used so that all individual variations of a specific term, when put into the knowledge base, are linked to the same geologic term. This would provide an individual ease of access to relevant information across countless numbers of maps and their related information within the knowledge base as it applies to their research. Traditional 2D geologic maps require the individual to analyze each map, and its related data, individually and reason through the connections between any and all geological features on the maps and the meanings between them. In the absence of geologic mapping ontologies, the individual themselves must discover the aforementioned connections and meanings using only their individual knowledge. Access to the knowledge base allows for the sharing of knowledge from many individuals and the connections and meanings to already be related within the ontology.

Geologic maps are a visual 2D representation of the 3D surface features of geologic units and the contacts between them that show the spatial and temporal information related to the geologic structures and other features of the units. This structural information includes measurement and orientation data whose meanings and interrelationships cannot be understood by conventional paper maps unless explicitly stated on the map or in an associated write-up. The same can be said of the geologic units of the map, an individual unit labeled in the key may have missing information such as the full composition of the unit or the relationship between the unit

and all other features on the map. For example, if the unit has foliations within its bedding the current method of geologic mapping is unable to relate the meaning of the foliation in the unit to foliations within other units, structures, and ages of the structures. This is where using a knowledge-based ontology would come in use. A semantic map system would allow formal description of the relationships among sets of information on the map, similar to the way a geologist looking at the map relates them. The purpose of allowing the ontology to do the reasoning is so one can query large amounts of spatial information within the knowledge base quickly, meaningfully, and efficiently. This would essentially make the geologic map intelligent by using a description logic-based software reasoning system rather than the current 2D image and key (legend). By doing this, a geologist can locate information related to their study area without having to analyze multiple maps, make the necessary connections themselves, and keep track of all relevant information. Also, a non-geologist attempting to understand what is being displayed on a map could simply select a geological feature and the ontology would be able to show them the information for that feature as well as how it relates to all other features on the map.

Currently, ontologies related to geological mapping are limited. One such ontology was developed by Hwang et al., 2012 and is designed to take pre-existing maps of Korea, and the information related to these individual maps, and compile them into a single semantic map. Their ontology would also reason through different unit names and descriptions to establish standardized information for the units. This was useful in combining maps that were created in English or Korean, along with maps that have overlapping areas where the units may be labeled differently yet have the same age and composition. The limitations of this ontology are that it was specifically created for mapping Korea and only applies to current existing maps. Though it

does build a backbone of how to set up ontologies that can take existing maps and semantically combine them, the ontology is limited to one specific region of the world. Another drawback of this ontology is that it does not take into account geological structures or data points (i.e. measurements or sampling locations); it only considers composition, age, unit name, symbol, and correcting minor issues caused by having dissimilar labeling. Within the ontology, a new map cannot be created in real-time, it must first be completed before it can be entered into the ontology and be automatically semantically related to existing information. The Ontology of Geological Mapping hopes to solve these limitations by providing a more robust platform for giving semantics to geologic maps.

Although the ontology created by Hwang et al., 2012 is not the only ontology that references geological mapping, it is currently the only one that applies to geological mapping in the way that this new ontology approaches the subject. Several of these ontologies are actually created to only perform site sampling, such as the ontology by Brodaric (2004). Other works that reference ontologies for geological mapping are not ontologies, but models for analyzing data sets and geological data that relates to geologic maps. Though they may concern ontologies for geological mapping, none of the above works are actual ontologies for creating geologic maps.

My project, the Ontology of Geological Mapping, is designed to work in the opposite direction of the ontology developed by Hwang et al., 2012. Instead of using pre-existing maps, and the mass amounts of information related to each individual map, and trying to input them into a knowledge base that will then create a semantic map, this ontology is designed so any map created is initially a semantic map, where all of the information about and within the map is already connected to all other parts of the map. Having this information within the knowledge base provides existing data that subsequent maps created using this ontology can be immediately

related to. This would, in a sense, enable future maps to be both standardized amongst one another and semantically related to one another. In addition, this new ontology could operate in all regions of the world and would only require minor recoding for special information that is specific to a given region.

Classical geological mapping will most likely remain as the standard form of mapping in the near future. This is due to instances when technology is limited in availability to an area of study or the device building a map gets damaged and an individual must revert back to making the classical map. In these situations, using the backbone of the ontology created by Hwang et al., 2012 to transform the maps into semantic ones would be beneficial. Though as technology becomes increasingly available and devices become better suited for field operation, this new ontology for geological mapping becomes more useful for the creation of future geological maps. This is due to its ability to store complex information that an individual can access and retrieve swiftly and effectively. The information is also semantic, so any piece of data is already connected in such a way that it can reason through its connection to any and all other pieces of data. This is far beyond what the conventional paper and digital maps are able to effectively portray, causing them to become outdated.

1.2 Scope

This ontology for geological mapping is designed for macro-scale mapping of lithostratigraphic units (from the scale of a supergroup down to a member), igneous and metamorphic rocks, and unconformities. It allows the mapping of geologic structures including faults, folds, and zones (e.g., shear zone and mineralized zone). The ontology also allows for the identification and mapping of finer features within these major stratigraphical and structural units such as foliation, sedimentary structures, and lineation. Measuring and determining the

orientation of mappable features and assigning chronostratigraphic ages to lithic units, as well as modeling relationships within and among rock units and their parts are made possible within the ontology through properties.

The current version of this ontology does not model the age relationships of the map units or structures; it only allows selecting a chronostratigraphic unit and geologic time. In this version, the ontology defines the general types of rocks, minerals, and fossils. When more detailed ontologies, relating to rock types, fossils, and minerals, are constructed in the future, they will be imported and reused in future versions of this ontology. Moreover, the ontology does not model the geologic processes or mechanisms that deform rocks, such as folding, tilting, intrusion, and metamorphism; only the spatial relationships among structures and rock units are defined through properties.

2 BACKGROUND OF ONTOLOGY

Ontology, as it relates to this project, is a computer coding knowledge model. This code model is used to express real objects or abstract concepts and their relationships. The term is "borrowed from philosophy, where ontology is a systematic account of existence" (Gruber, 1995). According to Gruber (1995), an ontology should be able to adequately communicate the meaning of defined terms and relationships. It should be able to do this in a coherent and clear way and anticipate the uses of the vocabulary.

By defining and relating the objects in an area of study with a standard vocabulary, it will become possible to integrate data from researchers who use the ontology to encode their data. An ontology makes it possible for a machine to access and interpret the meaning of concepts (e.g., fault, formation) and the relations among them (intrudes, sits unconformably on). The reason for developing an ontology is to share an understanding of information among people or between software, allow "reuse of domain knowledge, make domain assumptions explicit, separate domain and operational knowledge, and analyze domain knowledge" (Noy and McGuinness, 2001). This is done by specifying the relationships among concepts based on domain knowledge (Pundt and Bishr, 2002).

Ontologies enable computers to gather and organize information from different data sources in a quick and efficient manner (Zhong et al., 2009). Accessing and using diverse information (lithological and age databases, maps, charts, articles, and documents) related to an area from different sources would allow an individual to more completely analyze the geologic history of a particular area. This may not be necessary for simple searches in the case of limited datasets but is useful and time-saving when there are massive amounts of data sources and

information. Having an ontology that is built by modeling related or equivalent conceptual terms makes it possible to search, gather, and organize data from multiple sources more efficiently.

Ontologies are models of a common vocabulary that express knowledge about a specific subject and the terms within that subject. In an ontology, this subject is called the domain, which is the same as the discipline or field of study such as mineralogy and stratigraphy. A major part of creating an ontology is defining the vocabulary in accordance with the known relationships between the main domain concepts. An example of this can be seen in the work done by Zhong et al. (2009), which models the concepts related to rock fractures. Geologic structures, layers, deformation mechanisms, and faults are some of the concepts within the domain of structural geology which translate into classes in the ontology. For example, the class 'Fault' is a type of geologic structure with its own properties and relationships to other classes (e.g., 'Fold', 'Formation'). 'Fault' is a subclass of the higher-level class 'Geologic Structure'. By subclassing, a general term/class is taken and specialized into more specific terms/classes, thus forming a class hierarchy. Classes in a hierarchy are related through the 'isA' relation, for example, an individual of the 'Fault' class is an individual member of the 'Geological Structure' class. In addition to subclassing, classes are related to each other through object properties. For instance, individuals of the 'Fault' class are related to the individual occurrences of the 'Faulting' class. The OWL expression of this statement would be the triple statement: 'Faulting forms Faults'. This style of statement is known as a subject-predicate-object (SPO) triple statement. The property 'forms' relates the specific deformation faulting process to a fault. Such statements provide a semantic connection between different individuals within the domain.

Utilizing ontologies to perform geoinformatics research allows geoscience data providers, semantic web designers, and software developers to work together on shared topics, build data

models, and create semantic web applications for representing and managing their knowledge (Reitsma et al., 2009).

3 METHODOLOGY

This ontology is built using the knowledge of geologic mapping and the ontology coding language Web Ontology Language (OWL). Protégé 5.0.0 beta is the software used to encode the OWL ontology. The development of the classes and properties used are based on universal definitions of features and concepts used in geology along with practical experience concerning geological mapping.

The purpose of creating an OWL ontology goes beyond just setting up a standard class and property hierarchy. According to Gruber (1995), "OWL enables data to be connected to each other based on the domain knowledge which is based on special logics, such as description logic". Furthermore, "OWL is a Semantic Web language designed to represent rich and complex knowledge about things, groups of things, and relations between things. OWL is a computational logic-based language such that knowledge expressed in OWL can be exploited by computer programs, e.g., to verify the consistency of that knowledge or to make implicit knowledge explicit" (Michael et al., 2012). The point of semantic modeling by ontologies is to allow the machine to, in a sense, understand and reason, through inference, by drawing new implicit conclusions from what is explicitly stated in the ontology through the RDF triple (SPO) statements. This allows the user to quickly and effectively enter one's data (values for the classes and properties) into the knowledge base through an interface that uses a given ontology. The user can also extract parts or all of the related knowledge through queries.

The ontology of the knowledge of geologic mapping involves the modeling of structural and stratigraphic principles that are taught in the classroom along with practical experiences such as field measurements and mapping techniques. For example, a fault plane has an orientation that is described by the values of some properties (e.g., strike and dip). Orientation is a kind of

measurement (which as a concept models as a class in this ontology) with a set of attributes (properties) like ID and location. Moreover, a fault (an instance of the 'Fault' class) has parts and related objects such as fault blocks, fault zone, and fault rocks. Movement of the hanging wall and the displacement of the fault blocks define the type of fault, e.g., dip-, oblique-, or strike-slip, and their sub-types, e.g., normal, thrust or reverse. Information about the concept of a fault, and the rocks that it displaces, can be modeled in the ontology as universal classes by explicitly and formally describing all the necessary and sufficient information about individual (i.e., real) faults that share the properties of the 'Fault' class. Relationships among faults and other structures (e.g., fold, foliation), and the way that faults cross-cut stratigraphic units, unconformities, and igneous bodies will be defined in the ontology as properties. The type of faults, structures, stratigraphic units, unconformities, and igneous rocks are defined as classes.

Protégé is a major software where OWL coding can be written. Its design allows for the user to build classes representing domain concepts (e.g., 'Fault', 'Dike', 'Rock') and the properties that relate these classes (e.g., displaces, intrudes) as in the following triple statements: 'Fault displaces Rock' or 'Dike intrudes Stratigraphic Unit'. The program also offers pre-built property types, graphical displays, semantic reasoners, and several plugin tools. Within Protégé, it is possible to import other useful ontologies and export an OWL ontology into several other coding languages that can be used in other software. This allows an individual in need of the database but running a program that cannot script or read OWL, to still be able to use the ontology.

The development of the OWL coding for the ontology for geological mapping is created using actual experience, both instructional and personal, of field mapping and teaching individuals the techniques of field mapping. This is combined with textbook explanations and definitions for geological objects and the information relevant to geological maps. The SPO

statements of the ontology are constructed by considering any and all features on a geological map and then identifying the relationships or connections that a feature has to itself and all other features on the map. These relationships or connections are then simplified to the three-word design of an SPO statement. This is repeated for all features on a map until every possible SPO statement is made. Following this, each feature is rechecked and multiple questions are asked to determine if there are any missing SPO statements. This design is then able to be tailored to specific mapping regions with limited editing.

By combining these SPO statements from every feature on a geological map and coding them into Protégé as OWL code, the ontology takes form. After all of the necessary SPO statements have been entered, the Ontology of Geological Mapping is complete and ready to be tested and specialized for a specific mapping region of the world.

4 DESIGN

This ontology is constructed by establishing classes and the properties that relate a class to another or back to itself. The class hierarchy is developed first in order to ensure complete coverage of the necessary scope of geological mapping. The property hierarchy is built in accordance with the existing classes, related by domain and range (see below). The results of these connections are the SPO statements that are essential to the ontology's utility.

4.1 Classes

The class hierarchy is developed by creating classes on broad geological mapping concepts that were then able to be separated, if need be, into more specific subclasses. From this, classes exist at different levels, with the top-level ones being the broadest (e.g., Rock) and each lower-level class becoming progressively more specific (e.g. Igneous Rock, Intrusive Igneous Rock, and Granite). Figure 4.1 shows the top-level classes within the ontology of geological mapping.

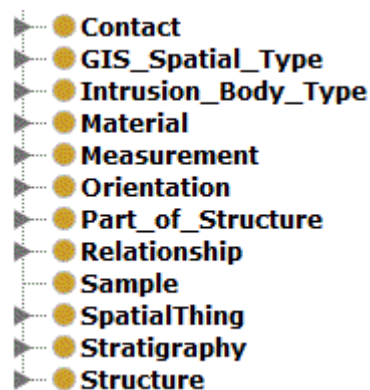

Figure 4.1 Screenshot showing the Top-Level Classes within the Geological Mapping Ontology

Arranged alphabetically, the first top-level class, 'Contact', is a broad term that defines the boundary between two or more geological features. Under the class 'Contact', there are

subclasses (Figure 4.2) that relate more specifically the contact type between specific types of geological features. The subclasses of the 'Contact' class can then be defined at lower levels such as the class 'Depositional Contact'; a contact between two lithostratigraphic layers. These contacts can further be classified as 'Conformable Contact' or 'Unconformable Contact', as shown. The hierarchy of the depositional contacts can still be expanded to very specific geological mapping contact types as shown in Figure 4.2.

Figure 4.2 Screenshot of the Top-Level Class 'Contact' and all Subclasses

For the rest of the classes within this ontology, the same style of subclassing is applied with the exception of the top-level classes 'SpatialThing', as it is imported from an ontology built by Basic Geo, and 'Sample', which has no subclasses. Figure 4.3 shows the classes 'Measurement' and 'Orientation', along with their subclasses. Creating the two subclasses for 'Measurement' enables separation of measurements between structural and stratigraphic features. Similarly, the class 'Orientation' is subclassed to define the orientation of a geological feature as either linear or planar. 'GIS Spatial Type' has four subclasses representing the different types of

input features within ArcGIS (Figure 4.4). This ontology has not yet been integrated with ArcGIS, but how it could was created anyway in the expectation that the interface created would allow ArcGIS to run the ontology.

Figure 4.3 Screenshot of the Top-Level Classes 'Measurement' and 'Orientation' and all Subclasses

Figure 4.4 Screenshot of the Top-Level Class 'GIS Spatial Type' and all Subclasses

Crucial to the mapping process is determining the make-up of a geological unit, what the formation is actually made of, that appears on a geological map. Possible material(s), such as rocks, minerals, and fossils, fall under the top-level class 'Material' as subclasses. Although water is not considered a geological unit, it exists as a subclass due to the fact that bodies of water are still a necessary component of a geological map. This is also the case for sediment; it is usually necessary to show areas of unconsolidated or loose sediment deposits within a map that cover large areas. Subclasses of 'Rock' allow one to identify what type(s) of rock a geologic unit is comprised of. Besides 'Rock', the classes 'Fossil' and 'Mineral', and their subclasses, were established to allow for a more in-depth selection of elements that a geologic unit may contain, which can aid in the identification of the unit. 'Rock', 'Fossil', and 'Mineral' were subclassed using the basic level of identification. The taxonomy of the class 'Material', up to three levels of subclasses, can be seen in Figure 4.5.

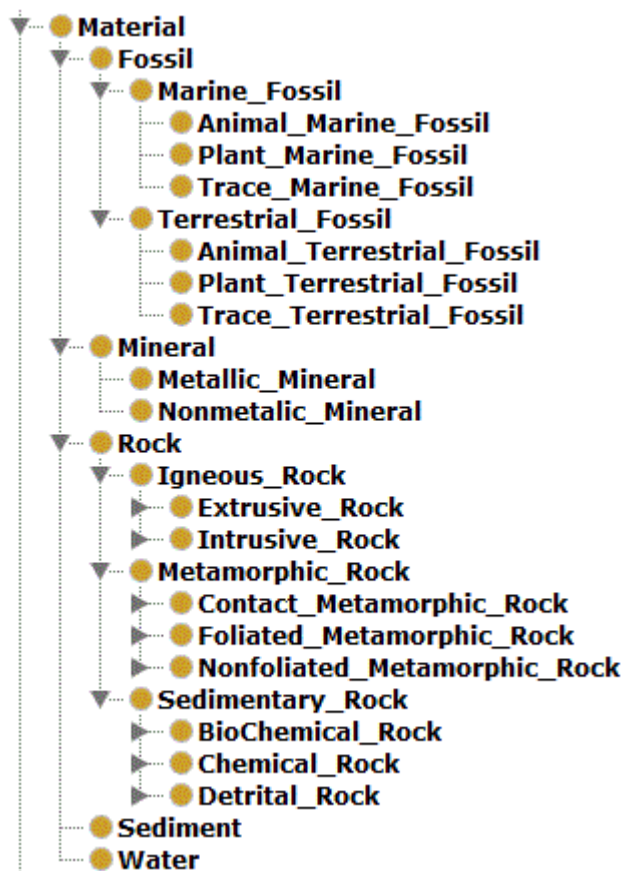

Figure 4.5 Screenshot of the Top-Level Class 'Material' up to three levels of Subclasses

Identifying the stratigraphy within an area is another major component to developing a geological map. By creating the top-level class 'Stratigraphy', and its respective subclasses, this information can be recorded within the ontology. Stratigraphy is comprised of two parts: age and stratigraphic unit. The class 'Chronostratigraphy' describes both the age period ('Chronostratigraphy Age') and the age type ('Chronostratigraphy Unit'). These two classes, and the multiple levels of subclasses they each contain, were created in accordance to the International Chronostratigraphic Chart designed by the International Commission on Stratigraphy. Subclasses for 'Chronostratigraphy Age' were made beginning with the broadest geologic age periods, i.e., Precambrian and Phanerozoic. Divisions of Phanerozoic exist as the

subclasses 'Cenozoic', 'Mesozoic', and 'Paleozoic', each of which can be broken down further. This method is continued until the geological time scale is reduced to the smallest geological time span (Age/Stage). In the same manner, the subclasses of 'Chronostratigraphy Unit' were created starting with the largest age type (Supereon). Subclasses of 'Chronostratigraphy Age' are instances of the respective 'Chronostratigraphy Unit' subclasses in which they occur. For the stratigraphic units, the class 'Lithostratigraphy' is created containing the subclass 'Lithostratigraphy Unit'. Using the terms for lithostratigraphy units (e.g., supergroup, group) the hierarchy is developed similar to 'Chronostratigraphy Unit'. The taxonomy of the class 'Stratigraphy' is expanded to four levels of subclasses in Figure 4.6.

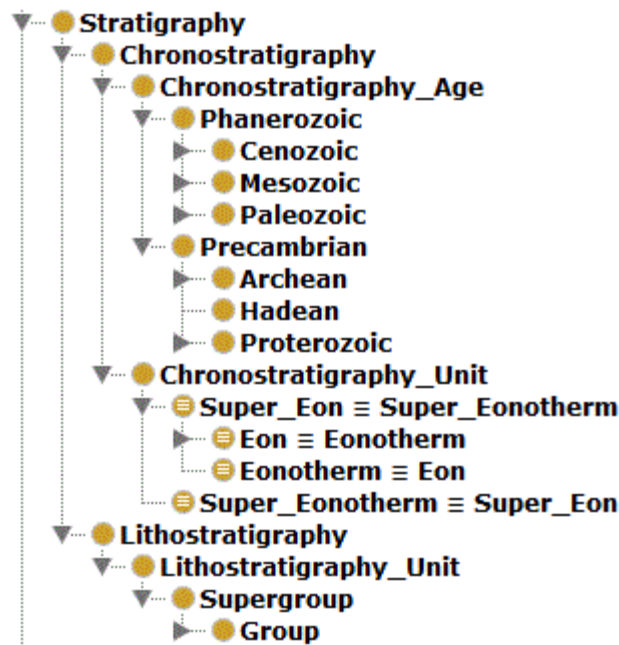

Figure 4.6 Screenshot of the Top-Level Class 'Stratigraphy' with both Subclasses 'Chronostratigraphy' and 'Lithostratigraphy' up to three levels of Subclasses

Just as there can be stratigraphic units on a map, intrusive units, such as dikes and batholiths, may also appear. These intrusive units make up the top-level class 'Intrusion Body Type', whose hierarchy can be seen in Figure 4.7.

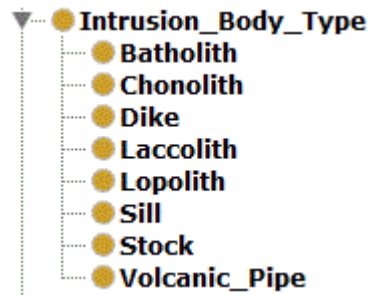

Figure 4.7 Screenshot of the Top-Level Class 'Intrusion Body Type' and all Subclasses

A geological map also has structural elements on it, which fall under the top-level class 'Structure'. These elements were first organized into three subclasses: 'Complex Structures' (structures that contain more than one part), 'Sedimentary Structures' (structures within sedimentary units), and 'Simple Structures' (structures that consist of one part). 'Sedimentary Structures' and 'Simple Structures' were divided into more specific subclasses on the basis of whether a structure is linear or planar. This process is continued until a class cannot be separated any further. 'Complex Structure' is divided into the three subclasses 'Fault', 'Fold', and 'Zone', each of which can continue to be expanded to very specific geological structures. The taxonomy for the class 'Structure', up to three levels of subclasses, can be seen in Figure 4.8. Some of the complex structures have specific parts that go with them, hence the creation of the top-level class 'Part of Structure'. This class includes 'Part of Fault' and 'Part of Fold', which contain subclasses that represent the specific parts a fault or fold may have. The classes that make up the taxonomy of 'Part of Structure' are shown in Figure 4.9.

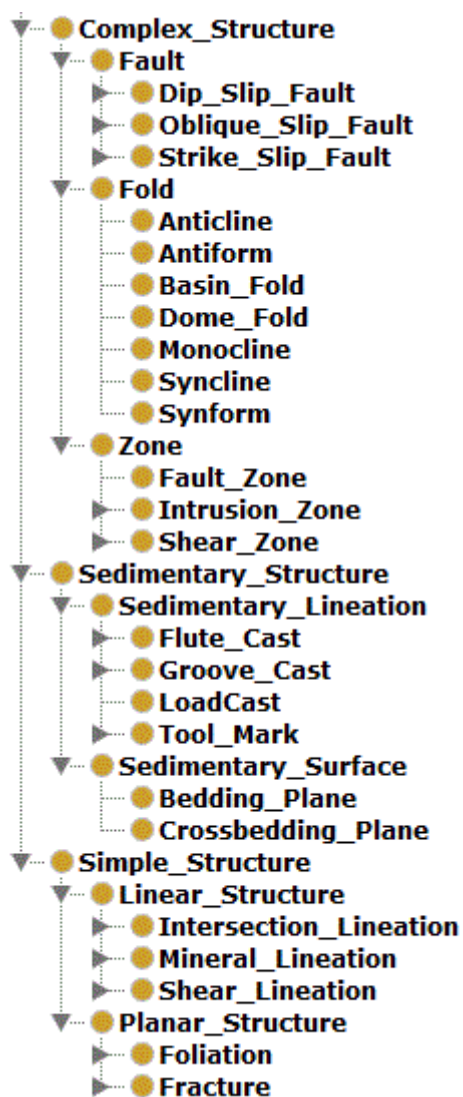

Figure 4.8 Screenshot of the Top-Level Class 'Structure' up to Three Levels of Subclasses

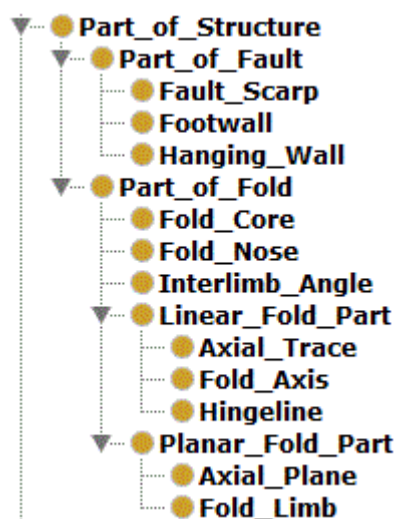

Figure 4.9 Screenshot of the Top-Level Class 'Part of Structure' and all Subclasses

The final top-level class is 'Relationship', which contains the different types of relationships any geological feature has to either another geological feature or itself. The first level of subclassing encompasses five still expandable classes. By alphabetical order, the first class is 'Containment Relationship', a class that contains subclasses that distinguish between the specific types of inclusions within a structural or stratigraphic unit. Beneath this is 'Geometrical Relationship', whose subclasses relate the orientation, movement amount, and shape of geologic units and structures. 'Intrusive Relationship' is the third class, and is divided into the subclasses 'Concordant' and 'Discordant' in order to select how an intrusive body relates to a stratigraphic unit. Under this is 'Spatial Relationship', a class divided into subclasses based on the directional movement of fault parts and the lateral extent of units. The subclasses of 'Topological Relationship' describe the type of adjacency a unit or intrusion has to another unit or intrusion, as well as what type of overlap a unit has based on whether the overlap is depositional or structural. Taxonomy for the class 'Relationship' can be seen, up to three levels of subclasses, in Figure 4.10.

Figure 4.10 Screenshot of the Top-Level Class 'Relationship' up to three levels of Subclasses

Now that all the classes have been developed and organized into their respective individual hierarchies, the full class hierarchy for this ontology is complete and contains all the features and relationships that a standard geological map is comprised of. It is also arranged in a manner so it is easy to navigate to where additional classes should be implemented within the ontology if they are needed for a specific region being mapped.

4.2 Properties

Properties are classified in two separate hierarchies; data properties and object properties. Data properties relate a class to a datatype such as a literal, with the class as the domain and datatype as the range for the property. These properties are used for classes that contain collected data or explicit information that must be recorded manually such as measurements or observations (e.g., as text or date). Object properties relate one class to another, the source class being the domain and the target class the range for the property. Both of these hierarchies were developed similar to the method of the class hierarchy, though in this case a specific property (e.g., dip-slip) is known as the subproperty of the more general property (e.g., displacement).

The data properties were created considering classes that require an individual to enter information gathered in the field in order for the class to have a use. This information could be measurement values like strike and dip, or unit information such as the unit's name. The hierarchy of the data properties can be seen in Figure 4.11. Within the hierarchy, the data properties have top-level properties that are general terms. For example, the top-level property 'faultDisplacement' has several subproperties with domains that hold for a specific class and ranges that have literal values collected in the field about a specific object. For example, the 'dipSeparation' property holds for the 'Dip Separation' domain class and has an 'xsd:string' range.

This range of 'xsd:string' allows for an individual to input the actual value of dip separation that a fault in the mapping area has.

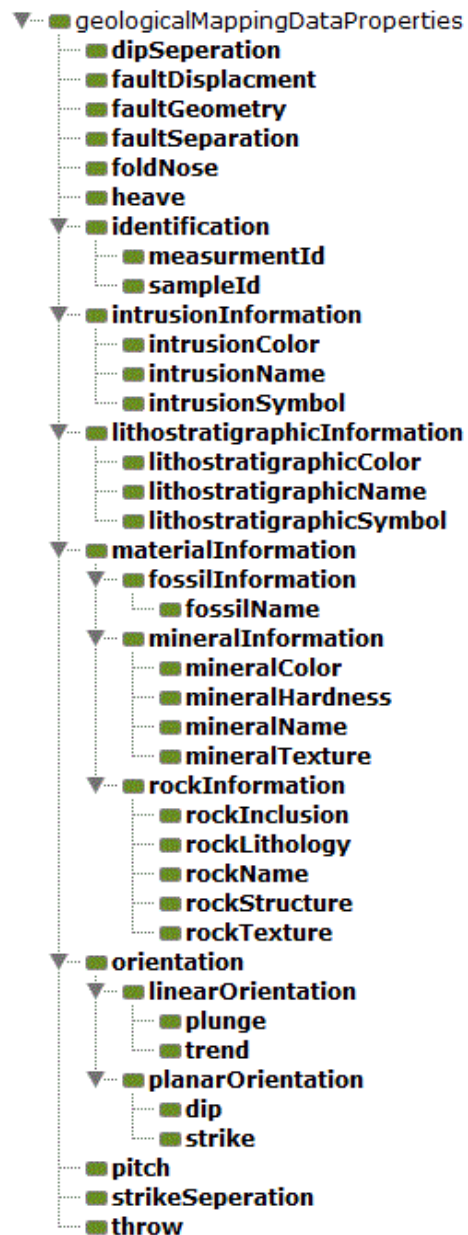

Figure 4.11 Screenshot of all the Data Properties within the Geological Mapping Ontology

Object properties were developed by reviewing every eligible class and identifying all geologic relationships. The hierarchy is developed in the same manner as the hierarchy of data properties, creating subproperties when possible. In this method, the top object type properties

are general terms for the more specific subproperties lower in the hierarchy. The majority of the object properties that relate classes together are based on the property design 'hasX', where X is replaced with the target class for the property such as the property 'hasFaultContact'. An example of this property used in this ontology is the SPO triple statement: 'Formation hasFaultContact Fault_Contact', which describes the fault contact for a formation. After creating the specific 'hasX' property, the inverse property is established with the format 'xOf'. The inverse property causes the domain and range to be switched so that the inverse of the SPO statement above now reads: 'Fault_Contact faultContactOf Formation'. An exception to this type of object property is the top-level property 'relativeAge', which has the two subproperties 'youngerThan' and 'olderThan'. These object properties are still inverses of each other but instead of stating what something has they show the age relationships between two geologic features (units, structures). Both of these object properties are transitive properties; if A is older than B, and B is older than C, then A is older than C. The hierarchy of object properties can be seen in Figure 4.12.

Figure 4.12 Screenshot of all the Object Properties within the Geological Mapping Ontology

Both the data and object property hierarchies were developed in a similar way as the class hierarchy. All properties needed for completing the SPO statements within geological mapping were created and then categorically combined as subproperties to develop their respective property hierarchies. Like the class hierarchy, the data and object property hierarchies have been organized so if a unique property is needed for a specific mapping region it is easy to locate where in the hierarchy that property belongs.

4.3 OntoGraf

OntoGraf is a plugin within Protégé that provides a visual display of the ontology by explicitly showing the properties and the classes or literals that they connect to. It allows to show a selected class, and its subclasses, at several levels. These newly displayed classes can then also be expanded to show the same. Properties that relate one class to another are shown as colored lines with an arrow pointing from the domain to the range of the property. Beside the graph is a key that explains the property types with colored lines. A few examples of OntoGraf can be seen in Figure 4.13 for the properties that hold for the 'Intrusion Body Type' class, and Figure 4.14 for the properties that hold for 'Lithostratigraphy Unit' class.

Figure 4.13 OntoGraf display of the properties that hold for the Class 'Intrusive Body Type'

5 DISCUSSION

The Ontology of Geological Mapping is designed and developed to provide a template for a knowledge base that will store data related to future geological maps. This is in contrast to the previous geological map ontology design by Hwang et al., 2012 that took pre-existing maps and their data and converted them into a knowledge base. The Ontology of Geological Mapping is also able to contain information that the other cannot, such as the relationships within and between geological features on a map. For this new ontology to become usable it requires building an interface that would allow a user (a mapper) to enter geologic map data from a specific area into a triple store (knowledge base), which is structured according to the ontology. Once this interface is developed, information can then be added to the knowledge base. This will both check for any holes in the ontology that need to be fixed and enable geological maps to have semantic reasoning within them.

The Ontology of Geological Mapping was built by formally describing all the necessary and sufficient characteristics and relations between geologic map elements (e.g., units, structures). The relationships between and within groups were established by working from the highest level to the lowest. The collection of these classifications and relationships exists as the class hierarchy in the ontology. Once all classes were established, properties were defined and related to the classes to provide semantics based on the domain knowledge. The data type properties were established to capture the values for specific map elements such as the name, symbol, and age of a specific lithostratigraphic unit. The object type properties were created to model the interrelationships among the instances of the same or different classes, for example, between a formation and another formation, a fault and rock unit, or a dike and an unconformity.

To further enhance reasoning through inference, the properties that relate the classes were also logically classified based on whether they were symmetric, inverse, transitive, or other types. Classes were also classified as disjoint with other classes if they could not share the same instances (e.g., solid and liquid).

This version of the ontology for geological mapping includes all the classes and properties necessary for a user in the field to build a logic-based geological map capable of reasoning through OWL's inference capabilities. For example, if a specific contact on the map is a thrust fault or unconformable, the ontology would infer that the thrust units are older than the fault and that the overthrust units, or the unconformable units, are younger than the units beneath the unconformity. 2D paper geological maps do not have such inference capabilities. Geologists themselves must use their own knowledge to draw implicit information from the map elements that are explicitly shown on the map. Thus, the main purpose of building this ontology is to enable geological maps to be created where the map elements are capable of relaying information in queries about what they are and how they relate to other elements on the map. This type of map is considerably more useful to a user than the standard paper or digital map of static points, lines, polygons, labels, and key. Semantic-aware geological maps built with this ontology, 'know' for example, that a mineralized zone along an intrusion is related to the intrusion; a foliation parallel to the axial plane of a fold may have formed with the fold; a dike cutting a fold which is overlain by an unconformity is younger than the fold yet older than the unconformity. Such reasonings and inferences cannot be made with the current paper and GIS digital maps without a geologist.

With all of the classes and properties related in this way, a geological map created using this ontology now enables all elements of the map to have semantic meaning to all other related

elements. All of this information would also be stored in a knowledge base, where it can be quickly related to any other relevant information such as an adjacent map. By having the information stored within the knowledge base, highly informative queries could be asked to identify complex information that an individual would like to know, for example, the command: "Locate all northwest dipping normal faults within the Montana area older than the Lower Devonian". Being able to find such complex information for a given area would permit an individual to discover geological information relevant to their study in a more quick and efficient manner than the current method of analyzing each map and its related write up individually.

The difference between this ontology and the previous geological mapping ontology (Hwang et al., 2012) is the approach that is taken to get the maps into a knowledge base along with when the map is created in relation to the knowledge base. In the ontology by Hwang et al., 2012, maps are first created and then entered into the ontology in order to develop the knowledge base. In effect, the individual maps are able to be combined to create a larger map of the Korea area and acquire semantic meaning. For the design of the Ontology of Geological Mapping, the ontology was built first. This way, a new map is instantly given semantic meaning and populates the knowledge base, allowing subsequent maps to have the ability to be immediately related to information already existing within the knowledge base.

Ontologies, like any software artifact, require update over time. In its current version, the Ontology of Geological Mapping is not capable of importing other ontologies. This can later be modified so that the ontology is able to reuse existing ontologies of geologic age and petrology. The two underdeveloped areas in this ontology concern the ages and material(s) of the geologic units. As previously stated, the materials were only developed at a basic level, and the ages only allow for selecting an age, not the relationships they have to one another. For example, the

current version does not include all types of rock that could apply to a rock unit (e.g., basalt, granodiorite). It also does not 'know' the relative ages of the geologic time elements, for example, that Cretaceous is younger than Permian. These issues can be eliminated in the future through the reuse (importation) of existing ontologies. Another shortcoming in this work is that the ontology has not been tested with real map data from a specific geologic area, due to the requirement that the ontology must first be constructed before an interface can. This interface is needed before the actual testing of the ontology can be done. This is necessary in order to discover issues related to the class and property hierarchies. Updating these missing areas with more complete ontologies related specifically to them, creating an interface, and adding information to test for holes are the next steps in making this ontology usable for an individual.

This ontology for geological mapping is not the end solution, it is just one part of what is needed for geological maps to become more usable and possess semantic meaning. By combining the Ontology of Geological Mapping, which gives future maps semantic meaning, with previous ontologies, where old maps are given semantics, all geological maps can now be entered into a knowledge base that provides quick and efficient queries and organization of information. As the ontology stands now, it fulfills its individual purpose of providing a base where it is possible for newly created maps to be input into a knowledge base within the limitations stated previously.

6 CONCLUSIONS AND FUTURE WORK

6.1 Conclusions

The main purpose of this thesis research project was to create a basic ontology for geological mapping. The ontology is developed with the purpose of creating a usable tool to enable individuals in the field to create knowledge-based maps on which geological features 'are aware of their semantic meaning based on the OWL language's logic-based constructs. Protégé is the program utilized to construct the OWL code related to the geological mapping ontology. The steps taken to create this ontology, along with the reasons behind the design, have been explained in earlier chapters. By building this ontology, an interface can be constructed that would allow future geological maps to be more useful and have more meaning than the current paper and digital maps.

6.2 Future Work

The following points are areas that can be pursued to expand upon this thesis project in the future:

- Import and reuse classes and properties of other related ontologies in the ontology for geological mapping.
- Develop an interface for this ontology to allow users to directly type in (i.e., assign) values for the objects (geological features) and their properties in the field.
- Test the ontology with real data from a specific mapping area.
- Expand the class and property hierarchies in the ontology.

try again

Revision 1.20 2009/04/20 12:42:11 timbl
Add Event (edited ages ago and never checked in), and location (following discussion
<http://chatlogs.planetrdf.com/swig/2009-04-20#T12-36-09>)

Revision 1.19 2009/04/20 12:36:31 timbl
Add Event (edited ages ago and never checked in), and location (following discussion
<http://chatlogs.planetrdf.com/swig/2009-04-20#T12-36-09>)

Revision 1.18 2006/02/01 22:01:04 danbri
Clarified that lat and long are decimal degrees, and that alt is decimal metres about local
reference ellipsoid

Revision 1.17 2004/02/06 17:38:12 danbri
Fixed a bad commit screwup

Revision 1.15 2003/04/19 11:24:08 danbri
Fixed the typo even more.

Revision 1.14 2003/04/19 11:16:56 danbri
fixed a typo

Revision 1.13 2003/02/19 22:27:27 connolly
relaxed domain constraints on lat/long/alt from Point to SpatialThing

Revision 1.12 2003/01/12 01:41:41 danbri
Trying local copy of XSLT doc.

Revision 1.11 2003/01/12 01:20:18 danbri
added a link to morten's xslt rdfs viewer.

Revision 1.10 2003/01/11 18:56:49 danbri
Removed datatype range from lat and long properties, since they would
have required each occurrence of the property to mention the datatype.

Revision 1.9 2003/01/11 11:41:31 danbri
Another typo; repaired rdfs:Property to rdf:Property x4

Revision 1.8 2003/01/11 11:05:02 danbri
Added an rdfs:range for each lat/long/alt property,
<http://www.w3.org/2001/XMLSchema#float>

Revision 1.7 2003/01/10 20:25:16 danbri
Longer rdfs:comment for Point, trying to be Earth-centric and neutral about

coordinate system(s) at the same time. Feedback welcomed.

Revision 1.6 2003/01/10 20:18:30 danbri

Added CVS log comments into the RDF/XML as an rdfs:comment property of the vocabulary. Note that this is not common practice (but seems both harmless and potentially useful).

revision 1.5

date: 2003/01/10 20:14:31; author: danbri; state: Exp; lines: +16 -5

Updated schema:

Added a dc:date, added url for more info. Changed the rdfs:label of the namespace from gp to geo. Added a class Point, set as the rdfs:domain of each property. Added XML comment on the lat_long property suggesting that we might not need it (based on #rdfig commentary from implementors).

revision 1.4

date: 2003/01/10 20:01:07; author: danbri; state: Exp; lines: +6 -5

Fixed typo; several rdfs:about attributes are now rdf:about. Thanks to MortenF in #rdfig for catching this error.

revision 1.3

date: 2003/01/10 11:59:03; author: danbri; state: Exp; lines: +4 -3

fixed buglet in vocab, added more wgs links

revision 1.2

date: 2003/01/10 11:01:11; author: danbri; state: Exp; lines: +4 -4

Removed alt from the as-a-flat-string property, and switched from space separated to comma separated.
