International Center for Public Policy Andrew Young School of Policy Studies

The Andrew Young School of Policy Studies was established at Georgia State University with the objective of promoting excellence in the design, implementation, and evaluation of public policy. In addition to four academic departments, including economics and public administration, the Andrew Young School houses eight leading research centers and policy programs, including the International Center for Public Policy.

The mission of the International Center for Public Policy (ICePP) at the Andrew Young School of Policy Studies is to provide academic and professional training, applied research, and technical assistance in support of sound public policy and sustainable economic growth in developing and transitional economies.

ICePP is recognized worldwide for its efforts in support of economic and public policy reforms through technical assistance and training around the world. This reputation has been built serving a diverse client base, including the World Bank, the U.S. Agency for International Development (USAID), the United Nations Development Programme (UNDP), finance ministries, government organizations, legislative bodies, and private sector institutions.

The success of ICePP reflects the breadth and depth of its in-house technical expertise. The Andrew Young School's faculty are leading experts in economics and public policy and have authored books, published in major academic and technical journals, and have extensive experience in designing and implementing technical assistance and training programs. Andrew Young School faculty have been active in policy reform in over 40 countries around the world. Our technical assistance strategy is not merely to provide technical prescriptions for policy reform, but to engage in a collaborative effort with host governments and donor agencies to identify and analyze the issues at hand, arrive at policy solutions, and implement reforms.

ICePP specializes in four broad policy areas:

- Fiscal policy (e.g., tax reforms, public expenditure reviews)
- Fiscal decentralization (e.g., reform, intergovernmental transfer systems, urban finance)
- Budgeting and fiscal management (e.g., local, performance-based, capital, and multi-year budgeting)
- Economic analysis and revenue forecasting (e.g., micro-simulation, time series forecasting)

For more information about our technical assistance activities and training programs, please visit our website at icepp.gsu.edu or contact us at paulbenson@gsu.edu.

The Distributional Effects of Devolution in the U.S. Welfare Reform

Luis Ayala,¹ Elena Bárcena-Martín² and Jorge Martínez-Vázquez³

December 2020

Abstract

The passage of the PRWORA in 1996 devolved responsibility for the design of welfare programs from the federal to state governments in the U.S. Some of the strategies implemented to achieve the main goals of the reform –promoting higher levels of labor participation and decreasing levels of welfare dependency– might have had the effects of reducing the protection received by the most vulnerable households and increasing differences in benefit levels across states. We estimate these effects using TANF data covering the two decades after the PRWORA's enactment. We measure the contribution of each state to inequality in adequacy rates. We provide an interpretation of the decomposition of the change in inequality in adequacy rates in terms of progressivity and re-ranking components, and we analyze the convergence in TANF adequacy rates. We also estimate the conditional convergence of adequacy ratios with respect to the change in labor participation, poverty rates, and caseloads. We find that differences in adequacy rates increased and that a downward divergence path took place ensuing devolution of welfare reform in the U.S.

Keywords: TANF, devolution, inequality, adequacy rates

1. Introduction

The passage of the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 (PRWORA) devolved responsibility for the design and implementation of welfare programs from the federal to state governments in the U.S. The motivation was to prompt states to create effective and innovative programs in order to promote higher levels of labor participation and decreasing levels of welfare dependency. As states were given more capacity to design their programs, the reform produced some kind of ‘laboratories of democracy’, using the phrase popularized by U.S. Supreme Court Justice Louis Brandeis.

Two decades later, considerable evidence has accumulated showing that in the process of welfare reform state and local governments have followed differing strategies and ended enacting very different programs. We have also learned that some states and localities have been more responsive to the new framework than others as they have taken more advantage of the opportunity to change the design of the programs. This diverse response became more evident with the Great Recession, renewing discussion about the potential social welfare costs in terms of the resulting differences in benefit levels across states. While the success of the programs should be measured mainly according to their initial objectives –promoting higher levels of labor participation and decreasing levels of welfare dependency– some of the strategies implemented might have had the effect of severely reducing the protection received by the most vulnerable households in some states. Inequality arising from the increasing differences of cash benefit levels across states has been also perceived as an additional distributional concern with potential welfare implications.

There are several avenues through which PRWORA can potentially increase differences in welfare benefits across states. States have broad discretion to determine policies while

complying with three federal requirements: fostering labor transitions through work requirements, imposing sanctions to those who fail to comply with the work requirements, and setting time limits on the receipt of benefits. States can also modify eligibility requirements, including asset and earnings disregards. Additionally, states have the ability to choose the intensity of benefits provided through the program.

A key issue is whether this increase in discretion for state governments has led to more generous welfare programs providing better protection or, in contrast, to more punitive welfare programs that offer lower level of benefits, stringer eligibility criteria and more restrictive work requirements. A second, less investigated, set of issues is whether decentralization has given rise to a substantial divergence in the level of benefits across states and what are the distributional consequences of this process. An important concern is whether higher levels of labor participation and decreasing levels of welfare dependency might have been obtained at the same time that benefits became lower and distributed more unequally across states.

These potential outcomes may have relevant implications in terms of inequality. First, higher adequacy in welfare benefits can be crucial to improve the situation of the most disadvantaged households and to some extent can represent the gains in social welfare resulting from public intervention. Some previous studies have proposed social welfare indices characterized in terms of the level of welfare embodied in a given distribution of adequacy rates (Ayala and Bárcena-Martín, 2018). Second, other studies looking at variation in the decentralized social safety net have found that it fosters new forms and dimensions of inequality and have used inequality indicators to measure these differences (Bruch et al., 2016; Meni and Wiseman, 2017).

Unevenness across states in adequacy rates have important distributional consequences for economically-vulnerable families. If we assume that the sufficiency of economic resources

provides to a certain extent an overall judgement of social welfare in a given country or region, we can look at the distribution of adequacy rates across states in a similar way to the standard analysis of inequality. According to the intensive literature on abbreviated social welfare functions (Sen, 1973; Chakravarty, 2009), a lower mean –in this case decreasing adequacy rates– and higher inequality –larger differences across states– yield lower levels of social welfare. In this way, social welfare does not only depend on the level of adequacy in each state but also on differences across states.

Decentralization might also give rise to a ‘race to the bottom’ with lower benefit levels and higher differences across states (Peterson and Rom, 1989; Shroder, 1995; Rom *et al.*, 1998; Figlio *et al.*, 1999; Brueckner, 2000; Saavedra, 2000; Berry *et al.*, 2003; Bailey and Rom, 2004; Baicker, 2005a, b), and, as a consequence, lead to considerable welfare under-provision (Gramlich *et al.*, 1982; Brown and Oates, 1987; Wheaton, 2000; McKinnish, 2005; Toolsema and Allers, 2014). While the evidence is somewhat mixed regarding the size and causes of the ‘race to the bottom’ effect, most studies confirm it. The empirical importance of such differences across jurisdictions has also been addressed in studies of some European countries with decentralized welfare related policies, such as personal social services in the UK (Revelli, 2006), local welfare benefits in Norway (Fiva and Rattsø, 2006), and the refugee placement program in Sweden (Dahlberg and Edmark, 2008).

As the evidence on lower benefits in real terms with respect to the levels before the reform in many states is increasingly robust, there has been renewed academic discussion over how a more decentralized system of welfare provision can lead to higher differences in welfare levels across states. As stressed by Chernick (2000), if more fiscal responsibility for redistribution is left to subnational levels of government, then states with weak fiscal capacity or limited preferences for

redistribution might choose benefits and levels of access that fall below some supposed minimum national standards of adequacy.

In the assessment of the 1996 welfare reform, a key issue is whether the federal government should have set up explicit distributional constraints on the process of maximizing labor participation and reducing caseloads. Therefore, a question commonly asked in the literature has been whether the different intensity across states in the trend of decreasing benefits has produced important inequalities in the protection provided by the program. Our paper enters at this point. We use some of the tools of the income distribution literature to evaluate the long-term results of the reform in terms of the differences in benefit levels across states in the Temporary Assistance for Needy Families (TANF) program.¹ We try to give an answer to questions such as how different are in fact state TANF adequacy levels or how have state TANF adequacy levels changed over time. While we are not the first to study both the decreasing trend in benefit levels in welfare programs in the US and the extent of differences across states, our work differs from most of the previous literature in that we analyze these differences using a distributional approach.²

Using data covering the two decades after the PRWORA's enactment we contribute to the development of a more comprehensive picture of the effects of PRWORA by analyzing how TANF adequacy ratios have evolved across time and how the relative level of adequacy of each state with respect to other states has changed. With this purpose we measure the contribution of each state to inequality in adequacy rates making use of the Gini index and interpreting this

¹ PRWORA instituted the Temporary Assistance for Needy Families (TANF) program, which became effective July 1, 1997. TANF replaced the Aid to Families with Dependent Children (AFDC) program—which had been in effect since 1935—and supplanted the Job Opportunities and Basic Skills Training program (JOBS) of 1988.

² A notable exception that uses a distributive approach to look at the dimensions and consequences of the decentralization of eleven federal-state programs is Bruch *et al.* (2016).

inequality measure in terms of deprivation. Second, using a dynamic perspective we evaluate the change in inequality and decompose it in changes in relative and absolute levels of adequacy following Silber (1995) and Jenkins and Van Kerm (2006). Third, we analyze convergence in adequacy levels under the unified framework proposed by Donghde and Silber (2016).

We find that differences in inequality levels across states increased and that a general process of degradation in the adequacy of these cash benefits took place during the time period under study. Besides adding new robust measures for both processes, we are first to provide new results identifying which states have contributed most to inequality. We also find that despite the lower reduction of benefits in states with initial lower benefit levels, this progressive decline was not translated into convergence in benefit levels due to large re-rankings between states. Using conditional convergence, our results also confirm that while there were clear gains in terms of labor participation, the adequacy of benefits decreased and, at the same time, differences across states increased. Although our aim is not to establish causality—given that there might be other confounding factors that we do not control for such as, interstate migration or changes in the business cycle over the 20 years our analysis covers—, our findings do add these two specific results to the broad set of outcomes of devolution to the states.

The remainder of the paper is organized as follows. Section two provides a brief summary of the main trends in benefit levels since the enactment of the reform. In section three we measure inequality in adequacy rates and identify the contribution of each state to total inequality. Section four decomposes the change in inequality in adequacy rates in terms of progressivity and re-rankings. In section five we analyze the issues of pro-poor growth and convergence through different measures. In section six we estimate the convergence of adequacy ratios with respect to the change in labor participation, poverty rates and TANF caseloads. Section seven concludes.

2. Trends in TANF Benefits

In 1996, the federal government passed legislation that transformed welfare provision in the US. The PRWORA replaced AFDC (Aid to Families with Dependent Children) program, which was a federal entitlement program providing federal funds to match states' expenditures on welfare programs, with TANF. The latter is a block grant that caps the dollar amount of federal funds to the states regardless of increases in case size. The introduction of TANF made state expenditures on cash benefits no longer subsidized at the margin (Marton and Wildasin, 2007). Although we only focus here on benefit levels, states can use TANF funds beyond the core areas of providing cash assistance and promoting work. Specifically, states can use TANF funds for a variety of services and support including: cash assistance, child care, education and job training, transportation, aid to children at risk of abuse and neglect, and a variety of other services to help low-income families.

Nationally, only about a quarter of TANF spending is on cash assistance, but states differ widely in their allocation of TANF dollars across cash and other categories.³ The states allocating a higher percentage of their TANF grant funds toward cash assistance are more likely to have supplemental minimum wages and lower unemployment rates, they are also ideologically more liberal, with a noticeably lower proportion of blacks residing in the state and a lower proportion of blacks on the TANF caseload (Hardy et al., 2019).

The new system of block grants gave states more capacity to select among policy parameters, but simultaneously imposing on them forceful mandates to promote work and reduce welfare

³ For example, only 7 percent of spending in Texas is on cash assistance, compared to almost 46 percent in California (Bitler and Hoynes, 2016b).

dependency.⁴ To qualify for TANF funds, states must comply with three federal requirements: i) state programs must emphasize work requirements to promote transitions from welfare to work; ii) state programs must include sanctions for reducing benefits to recipients who do not comply with the work requirements; iii) state programs must impose a five-year lifetime cap on receipt of benefits. As states responded to this new federal framework, their policy changes focused less on the amounts of reliefs offered than on the terms on which aid was given (Soss *et al.*, 2001; De Jong *et al.*, 2006).

Nevertheless, under the new framework, states have the ability to choose the intensity of benefits provided through their programs. Until the introduction of PRWORA, the states received the same federal match for their welfare spending regardless of whether this came from increased spending per recipient or the increased number of recipients. AFDC was jointly financed, with the federal matching rate depending on state income and with no cap on total expenditures. Quite the opposite, TANF is essentially a block grant, with a matching rate of 0 percent. Different authors have estimated the elasticities of benefit levels and caseloads with respect to federal subsidies (Chernick, 1998; Ribar and Wilhelm, 1999). The most robust results show that while states faced a marginal price (for both benefits and recipients) of around 40 cents on the dollar on average in 1995, TANF increased the price of either kind of spending to 1, representing an increase in both price margins of 120% (Baicker, 2005a).

It was not surprising then to predict that states with higher caseload-to-population ratios under AFDC in 1996 were going to adopt more restrictive policies under TANF system, including

⁴ To avoid an excessive reduction in welfare spending, TANF has a maintenance of effort (MOE) requirement under which states must spend at least 75 percent of the amount that they did prior to the welfare reform on benefits and services for members of needy families each year. Because of inflation, the real values of the federal block grants and the state MOE requirements have declined, falling by approximately 31 percent between 1997 and 2014 (Meni and Wiseman, 2017).

lower benefit levels. In general terms, PRWORA was a break from previous trends of welfare spending in the United States, which had grown both in absolute terms and as a percentage of GDP monotonically for 30 years prior to reaching an all-time high in 1994 (Moffitt, 1999). There is substantial evidence of a sharp decline in welfare caseloads since TANF was enacted in 1996. The first years after the PRWORA's enactment were marked by unprecedented drops in the number of families receiving cash assistance. The number of recipients dropped more than sixty per cent between 1994 and 2001 and continued to decrease in later years before slowing down and reversing slightly when the Great Recession began in 2008 (Weaver, 2014). In a number of states, TANF provides cash assistance to a much smaller share of poor families than the national data suggests. Most of the states that experienced a greater degree of caseload decline were those that engaged in second-order devolution –which allows local governments to exercise more discretion in the implementation of TANF (Kim and Fording, 2010).

According to these numbers, TANF has provided basic cash assistance to fewer needy families even when economic needs greatly increased, especially with the start of the Great Recession. The vast majority of states had declines in cash assistance during a very weak economic period, in sharp contrast to the huge increase in food stamp usage (Ziliak, 2016). There is also evidence showing that caseloads seem to have been less responsive to unemployment changes than they were twenty years ago. Using data on state caseloads from 1980-2009 and interacting unemployment rates and measures of welfare reform, Bitler and Hoynes (2010) found that the substantial changes implemented in welfare programs in the US during the nineties caused a decrease in the cyclicity of cash welfare. The available evidence also suggests that the lack of increase in caseloads is explained almost entirely by declines in take-up rather than declines in eligibility (Purtell and Gershoff, 2012). In addition, Bitler and Hoynes (2016a) confirmed the

lack of responsiveness of TANF to the Great Recession extending the data through 2012, and as a consequence extreme poverty became more cyclical than in past recessions.

Relatively less is known about the changes in benefit levels. Table A1 in the online appendix presents benefit levels for a family of three for 1996, 2000, 2005, 2010, and 2016 (using three-year moving averages) adjusted for inflation using the Consumer Price Index (Bureau of Labor Statistics).⁵ The purchasing value of benefits has fallen in most states. While differences among states are substantial, the amount of cash assistance has declined in inflation-adjusted terms since 1996 in almost every state –the exceptions are Wyoming, Maryland and Texas. Many states did not adjust benefits, allowing inflation to erode the benefits' real value. The mean moving average states' benefit level measured in constant terms dropped 24.85% in twenty years from \$388 in 1996 to \$292 in 2016. If the analysis is extended in time moving to AFDC data before the implementation of TANF in 1996, the real benefit declined from 24 to upwards of 70 percent between 1970 and 2012, and for the median state it fell by 51 percent (Ziliak, 2016). These changes in the level of benefits imply that if we only look at TANF benefits many families are more vulnerable financially today than decades ago.

Benefit levels vary substantially among states. For each year, the benefits in the five states with the highest benefits more than triple the benefits in the five lowest benefit states. In 2016, in the former group were Alaska, New York, California, Wisconsin, and New Hampshire; these states were also among the ten states with the highest benefits in 1996. At the bottom of the ranking are Mississippi, Tennessee, Arkansas, Alabama, and Louisiana, which were also among the seven states with the lowest benefits twenty years ago. Nevertheless, with the exception of the upper

⁵ Moving average data for 1996-1998 is named 1996, for 1999-2001 is named 2000, for 2004-2006 is named 2005, for 2009-2011 is named 2010 and for 2014-2016 is named 2016.

and lower tails of the states' distribution, the corresponding rankings of benefit levels are not constant. While some states have a similar position each year, there have been some remarkable re-rankings. When comparing the current ranking and that of 1996, thirteen states made jumps of five or more places. In general terms, the reduction of benefit levels in real terms was remarkably higher in the five states with the highest benefits than in the three states with the lowest ones.

A general approach to assess the economic sufficiency of the programs is to compare benefit levels with poverty lines. First, poverty alleviation is a primary objective of welfare benefits in most OECD countries, and when comparing benefit generosity across countries or states a useful starting point is to look at benefit levels relative to commonly-used poverty thresholds (Immervol, 2010). Second, as stressed by Cancian and Meyer (2004), poverty status remains a key measure of success for a number of reasons: the official poverty threshold is a standard, well-known measure of the sufficiency of economic resources, program eligibility is sometimes defined by poverty status, and, relative to measures of hardship, poverty status should be less sensitive to consumption choices and coping mechanisms that may reduce hardship but leave a family vulnerable.

For each state, the level of benefit for a family of three is compared to the official poverty line calculated by the Census Bureau.⁶ Alternatively, we have adjusted the benefits of each state with the cost of living for years for which SARPP Regional Price Parities by state are available (2008 onwards). Only for around 10% of the states the variation is greater than 10% and the orderings

⁶ The family of three is the size closer to the average number of persons in TANF families when the reform was implemented. The level of benefit for Alaska and Hawaii, where the cost of living is traditionally believed to be significantly higher than in other states, scaling factors of 1.25 and 1.15, respectively, are applied to the guideline for a family or household of three for the 48 contiguous states, and the results (if not already a multiple of \$10) are rounded upward to the nearest whole multiple of \$10.

are quite similar (with very little change in the states that are within the first ten or last ten positions of the ranking).

An alternative to the official poverty line is the new Supplemental Poverty Thresholds (SPM). These measure do take geographical differences in prices into account and the ranking of states by adequacy or benefit level generosity might be different. However, the earliest thresholds are for 2005 and to get back to 1996 it is necessary to make some strict assumptions (Fox *et al.*, 2015). Anyway, we have compared the results for 2016 using both the official poverty lines and the SPM and we find very similar rankings. Eight of the ten states with the highest rates in 2016 are the same with both thresholds; and we also find the same number in the case of the ten states with the lowest rates.

Table 1. Benefit as Percentage of Federal Poverty Level (for a family of three)

The picture of states and ratios considering benefits as a proportion of the federal poverty line is very similar to the previous analysis of inflation-updated benefits. The mean moving average states' adequacy rate dropped from 35.3 in 1996 to 26.2 in 2016. In more than two-thirds of the states the adequacy rate decreased over 20 per cent during this period. The only exceptions

escaping this decreasing trend were Maryland and Wyoming, where the level of benefits as a proportion of the poverty threshold increased more than 10 per cent.

Again, the differences are striking between the states with the highest ratios (over 40 per cent): New York, California, Alaska, New Hampshire and Wisconsin, and the states with the lowest ratios (below 15 percent): Louisiana, Alabama, Arkansas, Tennessee, and Mississippi. However, it seems that there is not a linear relationship between the reduction of the ratio and its initial level. In general terms, the reduction of benefits as a proportion of the poverty threshold was somewhat lower in the states that had the lowest ratios in the mid-nineties and the opposite occurred in case of the most generous states. However, there are important re-rankings –yet less relevant than in the case of absolute benefit rankings.

In short, both measures of benefit levels across states show that the protection provided by TANF has eroded in most states, leaving more families without sufficient income resources to meet their basic needs.⁷ The large differences observed in the treatment given to poor households (in identical conditions) in different geographic areas of the country are a source of inequality. In this sense, the increasing decentralization of welfare benefits implied by TANF has given rise to a problem of horizontal inequity. This latter problem lies at the heart of any discussion on the welfare consequences of devolving to the states broader discretion and responsibilities to determine antipoverty policies.

⁷ We could have used AFDC + Food Stamps or TANF+SNAP instead of only TANF. SNAP provides similar benefit levels nationally so it tends to smooth state differences a bit. We have replicated the analysis for 1996 and 2016 using TANF+SNAP instead of TANF and, even though adequacy rates are greater, the states rankings do not change significantly (Spearman rank correlation is 0.978 for 1996 and 0.992 for 2016, and the coefficients of correlation are 0.980 and 0.993, respectively) and our conclusions remain unchanged. Results are available from authors.

3. States Contributions to Inequality in Adequacy Rates

By considering the adequacy rate as a measure of the protection provided by each program is possible to use traditional indicators of inequality to summarize differences in the protection provided. We analyze between states inequality in adequacy levels with the Gini index. We take the state as the unit of observation —after all, it is the states that are the decision makers—, look at its adequacy level, and thus compare the rates. Note that this is properly a measure of between states inequality, since it compares states. It is “unweighted” because it is not intended to be a measure of inequality among citizens of USA, thus each state counts the same.

We take advantage of the interpretation of the Gini index of inequality in terms of relative deprivation to account for the contribution of each state to overall inequality. Relative deprivation allows to evaluate the level of adequacy of one state against the level of adequacy of other states in the U.S., which are taken as a sort of a benchmark. Relative deprivation refers to the situation of a single state, while inequality refers to the set of states as a whole. The desirability of obtaining indicators of relative achievements at the state level motivates the study of the contribution of each state to overall inequality through the relative deprivation analysis.

Let us assume a fixed homogeneous population $N = \{1, 2, \dots, n\}$ of n ($n \geq 2$) jurisdictions that in our framework are states that differ in the outcome of interest (adequacy rates). A feasible distribution Y is given by an outcome vector $(y_1, y_2, \dots, y_n) \in \mathbf{R}^n$ where y_i is state i 's adequacy, $i = 1, 2, \dots, n$, $y_1 \leq y_2 \leq \dots \leq y_n$ and μ is the mean adequacy. The deprivation, $I_D(y_i, y_j)$, of a state with adequacy y_i with respect to other state with adequacy y_j , where $y_j \geq y_i$, can be considered to be the adequacy differential (Hey and Lambert, 1980). . That is,

$$I_D(y_i, y_j) = \begin{cases} y_j - y_i & \text{if } y_j \geq y_i \\ 0 & \text{if } y_j < y_i. \end{cases} \quad [1]$$

The average deprivation of a state with adequacy y_i over the whole set of jurisdictions, $I_D(y_i)$, is

$$I_D(y_i) = \frac{1}{n} \sum_{j=1}^n I_D(y_i, y_j) = \frac{1}{n} \sum_{j=i+1}^n (y_j - y_i). \quad [2]$$

The average deprivation of the whole set of jurisdictions is I_D :

$$I_D = \frac{1}{n^2} \sum_{i=1}^n \sum_{j=i+1}^n (y_j - y_i) = \mu G, \quad [3]$$

where G is the Gini index. As we want to analyse relative inequality, we will compute deprivation in relative terms respect to the mean of the whole set of jurisdictions.

The contribution of each state to overall inequality is

$$C(x_i) = \frac{I_D(y_i)}{nI_D}. \quad [4]$$

Table 2. States Contribution to Inequality in Adequacy Rates and Gini Coefficient

State	1996	2000	2005	2010	2016

Gini index	0.199	0.198	0.201	0.202	0.205

Table 2 shows the Gini indexes for adequacy rates in 1996, 2000, 2005, 2010 and 2016 using three-year moving averages, and the corresponding contribution of each state to overall inequality in adequacy rates. The former information allows us to broaden and deepen the analysis of adequacy rates, since we consider not only the level but also the dispersion by evaluating the relative mean distance among states. Inequality in adequacy rates slightly increased (3% increase) from 1996 to 2016, showing that relative mean differences in adequacy rates across states is greater in 2016 than in 1996. A similar result was found by Bruch *et al.*

(2016) with a different indicator of adequacy –total benefit spending divided by a state’s average or total caseload. Although this result cannot be interpreted as causal evidence, it seems that since the mid-nineties –when the reform was enacted– inequality across states increased. In fact, the Gini index for AFDC/TANF benefit levels –University of Kentucky Center for Poverty Research (UKCPR) National Welfare Data– shows that while between the mid-1980s and the 1990s these differences decreased, in the subsequent period following devolution they increased, especially in the most recent years.

We simultaneously observe changes in the contribution of the states to overall inequality in adequacy rates showing that the distance with respect to states with greater adequacy rates were not the same from one year to the next. Alaska was the state with the highest adequacy rate in 1996 and 2000, and therefore contributes 0 to inequality, while California and New York played the same role in 2010 and New York alone in 2016. On the other extreme, we find Alabama and Mississippi in 1996 and 2000, and Mississippi and Tennessee in the remaining years.

Contributions to inequality were not stable along this time span. Washington and Rhode Island had the largest increases in contributions during 1996-2016. This means that these states increased their relative mean distance to the other states during this period of time. At the other extreme, New York, Wyoming and Maryland showed the largest reductions in contributions. Furthermore, in the cases of Maryland the contribution continuously decreased along these years.

In short, not surprisingly, once the devolution process of 1996 got started, inequality in adequacy rates increased. Given also that benefit levels as percentage of federal poverty threshold fell in most states, we can then conclude that if the evaluation of the reform were made exclusively in distributional terms, PRWORA yielded some identifiable well-being losses. In practice, however, this increase in inequality could have been the –perhaps, acceptable– cost to be paid for

the improvements in labor participation rates –which, in any case, cannot be attributed only to PRWORA but also to the strong macroeconomic expansion of the 1990s, as well as SNAP and EITC policy expansions (Gundersen and Ziliak, 2004), and overall lower welfare dependency.

4. Inequality, Progressivity and Re-Rankings in TANF Benefits

The dispersion observed in the adequacy rates has changed over time. This change can be due to a variation in the values of states' adequacy rates or to the variation in the relative position of the states in terms of adequacy rates. The two types of changes may not be independent since, for instance, a large increase in the rates will often be associated with an increase in rank, but it is informative to know which of the two changes is more relevant.

This differentiation does not only have academic interest. In the political sphere, in line with the models of yardstick competition, voters use information on public policies in the other jurisdictions as a yardstick in the assessment of their own government's policies (Besley and Case, 1995). In this sense, the changes in the relative performance of states are important not only because of their contribution to inequality but potentially also as a basis for individual decision making on voting, adding to their sense of economic security, and thus to their overall well-being.

Following Silber (1995) and Jenkins and Van Kerm (2006), we model the change in the Gini index of adequacy rates between some base year (0) and final year (1) for a fixed number of states.⁸ Letting G_t denote the Gini index for year t , the change in this measure can be written as

$$\Delta G = G_1 - G_0. \quad [5]$$

⁸ Jenkins and Van Kerm (2006) draw upon individual-level data. Even though ours may be a strong assumption, we also consider here the state as the unit of observation.

When the change in inequality is measured through the Gini index, an assumption of anonymity is made. It is not known whether the states had the same rank at time 0 and at time 1. In this section we delve into the analysis of the changes in the adequacy rates over time and decompose them into two components: one related to the changes in the states' adequacy rate and a second component related to the changes in their relative position in the corresponding distribution.

The change in inequality can be decomposed into two terms: V , summarizing progressivity (i.e. whether adequacy rates growth is greater in states with lower adequacy rates than in states with higher rates), and R , summarizing the re-ranking of states from the initial to the final year:

$$\Delta G = R - V \quad [6]$$

When every state experiences an equi-proportionate growth in the adequacy rate, $V=0$. When $\mu_1 > \mu_0$, μ_t being the mean adequacy mean adequacy at time t , and there is no equi-proportionate growth but it is more concentrated at the bottom of the distribution, $V > 0$. This can be considered a pro-poor growth in adequacy rates (progressivity). By contrast, if gains are more than proportionally concentrated among states with higher adequacy rates, $V < 0$. This would be the case of non-pro-poor growth in adequacy rates (regressivity). The opposite occurs when $\mu_1 < \mu_0$. The coefficient R summarizes the change in inequality due to reorderings of states from the initial to the final year. When there is no change in the relative positions, $R=0$, and $R > 0$ otherwise.

Table 3. Growth in Mean Adequacy Rates, Change in Inequality, Progressivity and Re-rankings

Years	Growth in mean	ΔG	V	R
1996-2016	-0.255	0.006	0.014	0.020
1996-2000	-0.035	-0.001	0.004	0.003
2000-2005	-0.097	0.003	0.001	0.004
2005-2010	-0.085	0.001	0.007	0.008
2010-2016	-0.065	0.003	-0.002	0.001

Note: ΔG : change in Gini coefficient, V: pro-poor growth; R: re-ranking from the initial to final year.

Mean adequacy rates fell during the period 1996-2016, and the progressivity index has a positive sign ($V > 0$) showing that the average reduction of adequacy rates was greater for states with higher adequacy rates (Table 3).⁹ During 1996-2000 there was a progressive reduction in adequacy rates that was partially counterbalanced by re-rankings, all resulting in a scant reduction in inequality. In the period 2000-2005 inequality growth stemmed mostly from re-rankings. Inequality scarcely increased in the period 2005-2010, but progressivity and re-rankings were high, in such a way that the progressive reduction in adequacy rates was totally counterbalanced by changes in relative positions. Finally, the period 2010-2016 is the only one with a non-progressive reduction in adequacy rates that was reinforced by re-rankings resulting in the greatest increase of inequality in adequacy rates. In general terms, we can conclude that the reduction in adequacy was greater in those with higher adequacy rates in 1996, placing some of them at lower adequacy rates than those of the states with the lowest initial levels.

⁹ The analysis was repeated using the generalized Gini coefficient (Donaldson and Weymark, 1980, 1983; Yitzhaki, 1983) for values of the inequality-aversion parameter between 1.5 and 4 (that give more weight to lower adequacy rates). As the general conclusions were the same for each case, we report results only for the Gini coefficient (parameter 2). Results for the other indices are shown in the online appendix, Table A2.

The decomposition analysis above therefore gives general support to the notion that the differences in adequacy rates increased mainly as the result of the changes in the positions of the states in the ranking of adequacy rates.

5. Inequality and Convergence in Benefit Levels

The previous analyses of inequality in benefit levels and the corresponding contributions of the different states to overall inequality help to confirm the increasing differences in adequacy rates across states.

A second and important issue that can be addressed using a distributional approach is whether or not devolution also yielded a ‘race to the bottom’ process. Given that benefit levels became lower in most states and that differences across states have become larger today than two decades ago, it can be expected that this process has been one of the long-term results of the reform. The issue of the relationship between the change in adequacy rates and how these changes are distributed among states is central in considering whether these changes gave rise to increasing or decreasing levels of convergence.

In order to identify the welfare gains associated with inequality and convergence in adequacy rates, first we make use of a graphical tool, the well-known Growth Incidence Curves (GIC) introduced by Ravallion and Chen (2003). The GIC captures the growth rate of a variable for every percentile of the distribution between two points in time. With the GIC we measure the growth of a given percentile, not a given state. We consider only a quantile, without knowing the identity of its participants. The GIC initially was formulated to measure whether growth in the lower quantiles is higher than in the mean income of the other quantiles, but it was soon extended in a variety of ways. Grimm (2007) applied these curves to the non-anonymous case (the same household or individual or state is followed and growth rates are plotted against the

quantiles of the initial distribution) and referred to it as the Individual Growth Incidence Curve (IGIC). In addition, Grosse et al. (2008) used these curves to examine whether growth in a given variable (non-income dimension) was greater for lower centiles by defining the Non-Income Growth Incidence Curve (NIGIC). We make use of the NIGIC –in its Anonymous and Non-Anonymous version– to obtain a graphical analysis of the distribution of growth in adequacy rates.

In the non-anonymous case, we arrange the states by increasing order of adequacy level in the initial year, $t - 1$, and compute the change in adequacy rates for the same state at two periods, t and $t - 1$,

$$g_{it} = \left(\frac{y_{it}}{y_{it-1}} \right) - 1, \quad [7]$$

where y_{it} and y_{it-1} refer to the adequacy rate of state i at times t and $t - 1$ in a population of n states. If g_{it} is a decreasing function for all i , then inequality falls over time for all inequality measures.

In the anonymous case, we arrange the states by increasing order of adequacy level in the initial year, $t - 1$, and also in the final year, t , and compute the growth rates for those states in the same position in $t - 1$ and in t . Note that states do not need to be in the same position in both points in time. The anonymous-NIGIC can be estimated using the change in the adequacy rates y_t for each quantile p at two periods, t and $t - 1$,

$$g_t(p) = \left(\frac{y_t(p)}{y_{t-1}(p)} \right) - 1. \quad [8]$$

If $g_t(p)$ is a decreasing function for all p , then inequality falls over time for all inequality measures. It must be noted that the use of anonymous-NIGIC is based on a cross-sectional

comparison of the marginal distributions at the beginning and end of the time period considered.

Therefore, we omit the issue of mobility from the evaluation of growth rates. If we want to

consider mobility in the evaluation of growth rates, we should use the non-anonymous-NIGIC.

Figure 1. Non-anonymous and Anonymous Growth Incidence Curves of States Adequacy Rates

Note: Non-anonymous case: growth rate in adequacy in a state in 2006 relative to the adequacy corresponding to the same state in 2016. Anonymous case: growth rate in adequacy of a state ranked i in 2006 relative to that of a state with the same rank i in 2065.

Figure 1 shows the Non-anonymous and the Anonymous Growth Incidence Curves for the adequacy rates. The figure confirms our previous conclusion that the greatest reduction in these rates during the period 1996-2016 was in the states which had higher adequacy rates in 1996. Nonetheless, the analysis in an anonymous setting shows that the highest reduction in the adequacy rates during the same period took place in the lower centiles. This apparent contradiction is due to the fact that the greatest reduction in adequacy rates were experienced by the states with higher initial adequacy rates, and the reduction was such that placed some of these states close to the bottom of the distribution of adequacy rates at the final year

Last, we compute distributional change indices. First, we use Silber's (1995) measure of distributional change to assess inequality in growth rate. Second, following Donghde and Silber (2016), we estimate the index of distributional change that summarizes convergence in a non-anonymous case, C_N . This index measures the degree of β -convergence across states in the adequacy rate —the degree to which states with lower adequacy rates increase (decrease) faster (slower) than states with higher adequacy rates. This methodology allows the estimation of measures of distributional change even when the number of observations is limited and only available in aggregate form. This methodology is particularly useful in the analysis at the state level because of the relatively small number of observations (51, from 50 states plus the District of Columbia). In such a case, traditional econometric approaches to convergence analysis should not be used. We also compute the index of convergence in the various centiles in the anonymous

case, C_A , which reveals the extent of σ -convergence in adequacy rates (reduction in the dispersion of adequacy rates).

Table 4. Inequality and Convergence in Adequacy Rates

		Inequality of adequacy rates growth	Convergence of adequacy rates
1996-2016	Non-anonymous	0.089	-0.013
	Anonymous	0.033	0.008
1996-2000	Non-anonymous	0.029	-0.002
	Anonymous	0.020	-0.002
2000-2005	Non-anonymous	0.033	-0.008
	Anonymous	0.020	-0.006
2005-2010	Non-anonymous	0.045	-0.009
	Anonymous	0.025	-0.001
2010-2016	Non-anonymous	0.024	0.002
	Anonymous	0.017	0.002

Note: Non-anonymous case: adequacy in a state in 2006 is compared to the adequacy corresponding to the same state in 2016. Anonymous case: adequacy of a state ranked i in 2006 is compared to that of a state with the same rank i in 2016.

In general terms, we find that the estimated values of the various non-anonymous and anonymous indices differ in sign for the period analyzed (Table 4). As we remarked above, this is so because the different approaches to identification of states lead us to different conclusions. Along the entire period, inequality in growth rates did not show a clear tendency, displaying a slight upward slope in the anonymous case and a clear upward slope in the non-anonymous case, and in both cases there is a reduction in inequality for the last part of the period analyzed.

The comparison of adequacy rates in 1996 and 2016 reveal a negative non-anonymous convergence of adequacy rates meaning that on average adequacy levels in states with greater initial values decreased at a higher rate than in those with low initial levels so there is convergence over time. Such a case corresponds to what in the literature is characterized as β -convergence. This is the case for all the sub periods analyzed except for the last one.

In the anonymous case we look at the rates of growth in the various centiles. It is useful for assessing σ -convergence in adequacy rates. The finding that the convergence index is positive in the anonymous case for the overall period implies that on average the reduction in the rates were greater in the lower than in the higher centiles so that inequality increased (σ -divergence).

Nonetheless, there is σ -convergence in each sub period, except in the last one.¹⁰

In summary, the distributional convergence analysis for the entire period confirms that there was some kind of catching-up by states with lower benefit levels with the states with the most generous ones. Nevertheless, this process of rapprochement was mainly led by a general trend of reductions in benefits that were especially marked in the states with higher adequacy rates before PRWORA was enacted. This result is related to the change to a new system of block grants. As the Federal Government shifted from matching rates to a flat lump sum, the effective price of aid per dollar spent went up for those states that had higher benefits and matching rates in the previous regime. As different authors have stressed, it is not surprising to find a larger than proportional decrease in adequacy rates for those previously higher spending states (Baicker, 2005a; Fetter, 2016).

Therefore, the analysis supports the notion of some sort of race-to-the-bottom effect, which may be associated with marginal distributional social welfare losses that could reduce the gains involved by the improvements in labor participation and caseload numbers. Nevertheless, the downward convergence observed could be also caused by a variety of other factors. As mentioned above, PRWORA increased the marginal cost of each dollar states spend on welfare

¹⁰ This is known as the Simpson paradox. It refers to a phenomenon in which a clear direction emerges in individual data sets but disappears or reverses with aggregated data. The effect was identified by Simpson (1951), but had been mentioned earlier by Pearson et al. (1899) and Yule (1903).

beyond that covered by the block grants. In summary, our results, while consistent with a race-to-the-bottom, could also come from other factors.

6. Conditional Convergence of Adequacy Rates

All the analyses conducted in the previous sections coincide in showing that lower adequacy rates, higher inequality across states, and a downward divergence path are the general outcomes of the reform when looking at the differences in the protection received by the most vulnerable households through TANF. To some extent, these results leads to assume that, as mentioned above, one of the consequences of welfare reform was a loss of social welfare in the terms mentioned above.

However, when it comes to public policy discussions of the welfare reform enacted in 1996, promoting higher levels of labor participation and decreasing levels of welfare dependency were the main goals of the reform. In the wake of this landmark welfare reform, a widespread concern was strengthening work incentives and reducing TANF caseloads. These outcomes have been discussed thoroughly in the literature and researchers have consistently documented that welfare reform reduced participation in TANF program and increased employment —also driven from historically strong economic growth and the expansion of other benefits— and earnings of single mothers (Ziliak, 2016). These improvements have also led to other positive results in other dimensions relevant to well-being —health, child outcomes, family composition, consumption, savings and many other outcomes— that have been consistently summarized by different authors.¹¹

¹¹ See, for example, Moffitt (2003), Grogger and Karoly (2005), Blank (2009), and Ziliak (2016).

Therefore, while adequacy rates and differences across states are a reasonable characterization of the reform's outcomes, in terms of social welfare those original objectives of the reform cannot be ignored. To the extent that higher levels of labor participation should yield higher levels of social welfare, possible inferences drawn from a partial view of the whole picture should be viewed with skepticism. The very idea that TANF did not have an antipoverty objective it is hardly sustainable. The question is whether the perspective adopted to lower poverty by increasing self-sufficiency, employment, and two parent family formation, could affect the adequacy and inequality of TANF benefit levels. We want to ask whether the states where labor participation increased the most were also those states in which the reduction of benefit levels was larger. Regardless of the possible causal relationships —difficult to infer from the distributive approach adopted in this paper— the fact of connecting the two types of results broadens the possibilities for interpreting the long-term effects of the welfare reform.

In order to get a further insight into this relationship we extend the previous analysis estimating convergence of adequacy ratios with respect to other variables (Donghde and Silber, 2016). This means that we compare the change in other outcomes with the change in adequacy rates. In this way, we examine whether progress in adequacy rates has been more favorable in those states with better outcomes in other variables. To have a broad vision of these interdependencies we make convergence conditional on some of the variables that have been highlighted as the most relevant outcomes of the reform:

- The change in the number of hours worked by single mothers as an indicator of the success of the reform in terms of improving labor participation.
- The change in poverty rates for single-mother households as a direct indicator of changes in living standards.

- The change in the relative number of TANF caseloads as an indicator of the reduction in welfare dependency.¹²

The information on the last variable was obtained from the Office of Family Assistance and the USDA. The number of hours worked by single mothers was estimated using the Current Population Survey (CPS). Mothers were identified in the survey and single mothers were defined as mothers with no other parent in the household where the child lives. The number of hours worked is defined as the usual number of hours per week the respondent reports being at all jobs, over an unspecified time period. The average number of hours worked by single mother by state were computed using the CPS for years 1996 and 2016, and the difference was estimated. Poverty rates for single mothers is the proportion of single mothers that are identified as poor using the Official Poverty Status, a variable of the CPS constructed by IPUMS. Table 5 provides general support to the notion that the main objectives of the reform were achieved. On average, looking at the results for all states, the number of hours worked by single mothers increased by more than 62% between 1996 and 2016.¹³ Regarding welfare dependence, TANF caseloads decreased more than 70% in the same period. The changes in the poverty rates of single mothers were, however, more modest, with a reduction of 5%.

Table 5. Convergence of Adequacy Rates Conditional to Different Variables, 1996-2016

	Mean change	Conditional convergence
Hours worked by single mothers	62.6	-0.0033
Poverty rates of single mothers	-5.4	-0.0255
TANF caseloads	-70.8	-0.0091

¹² An alternative indicator could be the take-up rate in each state. It might be the case that states with low benefit levels decreased them but made them available to a higher share of low-income people. Estimating these rates is an undertaking that lies beyond the scope of this paper. Nevertheless, by looking at the caseloads we are considering this kind of relationship.

¹³ Scatter plots showing the change in TANF adequacy rates against changes in these 4 variables are shown in Figure A1 in the appendix.

The third column of Table 5 presents estimates of conditional convergence rates in a non-anonymous setting. The conditioning variables are the changes in the three variables listed above. Several points are worth mentioning. First, the sign of the indexes of conditional convergence with respect to the changes in the number of hours worked by single mothers, the poverty rates for single mothers, and TANF caseloads are all negative. This means that there is β conditional convergence and the results for adequacy rates can be interpreted depending on the change in the mean values of the other variables in the period studied.

Regarding the primary outcome of the reform –improving labor participation–, in general terms, given the small negative value of the conditional convergence measure, the states where TANF adequacy rates decreased more seems to be the ones in which the mean hours worked by single mothers increased more. Quite the opposite, in the states where the reductions in TANF adequacy rates were more modest the hours worked by single mothers increased less. Therefore, this result is in line with the fact that higher levels of labor participation were achieved in parallel with a reduction of benefit levels, the positive effect on social welfare levels of higher employment being partially offset by the reduction in the protection of the most vulnerable households.

In the case of the poverty rates for single-mother households, we find that in general terms the states that experienced higher reductions in TANF adequacy rates were also those in which poverty rates decreased less. In contrast, in the states where TANF adequacy rates decreased less poverty rates decreased more. Not surprisingly, this result reinforces the idea of the high cost in terms of living standards of a strategy based on the reduction of benefit levels to reduce the dependency on the benefits. As stated by different authors, though it still has an impact, the

effects of TANF on single-parent families has shrunk while those of other programs like EITC have remarkably increased (Ben-Shalom et al., 2012).

A similar conclusion arises from the analysis of the interdependencies between the changes in the adequacy rates and the caseloads. In general terms, the states with greater reductions in TANF caseloads had a smaller decreases in adequacy rates, while those with lower reductions in the caseloads had greater reductions in adequacy rates. This result is related to the block grant system that caps the dollar amount of federal funds to the states regardless of increases in case size, shifting to the states all the costs resulting from an increasing number of recipients. Under the previous matching-grant system of AFDC, states only covered a fraction of additional spending. As stated by different authors (Stiglitz and Rosengard, 2015; Ziliak, 2016), the 50 percent matching rate had effectively lowered the “price” of welfare, and under TANF this price is higher. Higher caseloads imply that the cost of a dollar increase in the benefit level is greater. If the states want to maintain the level of spending around a certain level, they may choose between reducing TANF benefit levels or reducing caseloads. In practice, some studies found that the substantial changes implemented in welfare programs in the US caused a decrease in the cyclical response of cash welfare (Bitler and Hoynes, 2010; Loprest, 2012), confirming the importance of the price effect. The lack of cyclical response of TANF is likely attributable to the block-grants received by the states, that are fixed in nominal terms each year regardless of macroeconomic conditions (Bitler and Hoynes, 2016b).

It could be argued that with higher labor force participation, more income is earned and therefore TANF benefits could be less needed. However, in practice, the available data show that the coverage of vulnerable households did drop to low new levels in most states. In 12 states, 10 or fewer families for every 100 families in poverty receive cash assistance, while in 13 other states,

30 or more families receive cash assistance from every 100 families in poverty (Center on Budget and Policy Priorities, 2016). When TANF was enacted, nationally, 68 families received assistance for every 100 families in poverty; that number has since then fallen to just 23 families receiving assistance for every 100 families in poverty. Sherman and Trisi (2015) found that while in 1995 AFDC removed 2.4 million children from deep poverty —having income below 50 percent of the poverty line— in 2010, TANF removed 600,000 children. There is growing empirical evidence showing that the most economically disadvantaged families have been less protected by the safety net over time (Bitler and Hoynes, 2016a; Hardy, 2016).

Therefore, against the well-established gains of higher levels of labor participation and decreasing levels of welfare dependency, a fair assessment of the effects of the 1996 reform must take into account the lower adequacy rates and higher inequality of benefits across states that followed the assignment of greater responsibilities to the states.

7. Conclusion

The increased ability of states to set TANF benefit levels and eligibility conditions as a result of the welfare reform that was enacted in 1996 has attracted great attention from researchers and policymakers. While changes in labor participation rates and increases in self-sufficiency or less transfer dependency –the stated main objectives of the reform– have been the subject of much attention in the literature, there has been much less attention paid to what the costs of that reform may have been. This latter research is needed to provide a more balanced assessment of the impact of the reform in terms of distributional costs. The past two decades have witnessed an intense debate over the long-term effects of the reforms on the under-provision of welfare benefits and the likely ‘race to the bottom’ process that would accompany the reform with lower benefit levels and higher differences across states. While previous work has provided evidence of

the existence of a ‘race to the bottom’ effect and a general reduction in TANF levels, after many years of research, until now we have had relatively little insight into what have been the potential distributional costs of PRWORA.

The potential effects of the 1996 devolution process on inequality across states raise numerous interesting questions. In this paper, we have focused more narrowly on the measurement of these inequalities across time using a distributional approach. By considering alternative distributive approaches to identify the different avenues through which inequality in states’ benefits could have increased, this paper contributes to the development of a more comprehensive picture of the long-term results of the 1996 reform.

According to our results, the purchasing value of most benefits has fallen drastically since PRWORA was enacted, with the amount of cash assistance declining both in inflation-adjusted terms and as a proportion of the federal poverty line in almost every state. As a result, the capacity of the programs to alleviate poverty has been severely limited and extreme poverty is more cyclical now in the U.S. than in past recessions. During the last two decades, differences in benefit levels between the higher and lower generous states have been very large. Furthermore, with the exception of the upper and lower tails of the states’ distribution the corresponding rankings of benefit levels have not been constant. Additionally, the reduction of benefit levels has been remarkably larger in the states with prior higher benefits than in those with prior lower ones. Despite this distribution of the reduction in adequacy rates, we find that welfare reform increased inequality in adequacy rates across states at the same time that the amounts received by poor households were reduced.

One contribution of the paper has been to identify the precise effect of each state’s reform on overall inequality in benefit levels across years and states. While contributions to inequality were

not stable along the different time periods, it is clear that some states increased their contributions to inequality between 1996 and 2016 (Washington and Rhode Island) –with a great distance with respect to the most generous states– while the opposite occurred in other states because of the positive growth in their adequacy rates (New York, Wyoming and Maryland).

In general terms, almost all the states experienced a reduction in their adequacy rates that can be termed as being pro-poor, as in the states with lower adequacy rates in the mid-nineties reductions were lower than in the rest of the states. However, changes in the position of each state in the distribution of adequacy rates (re-rankings) made overall inequality to increase.

Last, another finding from our distributional approach is to confirm that devolution can be associated with a ‘race to the bottom’ effect among states in the longer term. The distributional convergence analysis shows that the states with lower benefits at the beginning of the devolution period had smaller reductions in benefit levels while the states with largest benefits at the beginning had the largest reductions in benefits. The results show that there is downward anonymous divergence, meaning that on average the reduction in the rates were greater in the lower, rather than in the higher, centiles causing inequality to increase..

In short, the assessment in distributional terms of the system that devolved to the states more capacity to select among policy parameters is a negative one. Yet knowing that the major objective of the reform was to foster transitions from welfare to work, the increased capacity of states to achieve this goal also had significant negative distributive impacts: lower adequacy rates, higher inequality across states, and a downward divergence path. All these lead us to conclude that the PRWORA reform of 1996 yielded some distributional costs, which one would have to put in the balance when assessing the gains in labor participation rates and reduced

dependence. To this point, there has been little recognition of those costs in the overall assessment of the success of the PRWORA reform.

In sum, our results show that the achievement of the main outcomes was not neutral. The states where TANF adequacy rates decreased more were also the ones in which the hours worked by single mothers increased more and reductions in poverty for these households were less. In other words, the welfare gains from the higher labor participation coincided with a reduction in the intensity of protection, although partially offset by the improvement in other benefits. It is possible that in order to improve labor incentives, the reduction of benefit levels may have been inevitable, but these policies had important distributional consequences that must be taken into account for an overall evaluation of the impact of the reform.
